

COMPREHENSIVE SERVICES

We offer competitive repair and calibration services, as well as easily accessible documentation and free downloadable resources.

SELL YOUR SURPLUS

We buy new, used, decommissioned, and surplus parts from every NI series. We work out the best solution to suit your individual needs.

 Sell For Cash  Get Credit  Receive a Trade-In Deal

OBSOLETE NI HARDWARE IN STOCK & READY TO SHIP

We stock **New**, **New Surplus**, **Refurbished**, and **Reconditioned** NI Hardware.

Bridging the gap between the manufacturer and your legacy test system.

Important Information

Warranty

The media on which you receive National Instruments software are warranted not to fail to execute programming instructions, due to defects in materials and workmanship, for a period of 90 days from date of shipment, as evidenced by receipts or other documentation. National Instruments will, at its option, repair or replace software media that do not execute programming instructions if National Instruments receives notice of such defects during the warranty period. National Instruments does not warrant that the operation of the software shall be uninterrupted or error free.

A Return Material Authorization (RMA) number must be obtained from the factory and clearly marked on the outside of the package before any equipment will be accepted for warranty work. National Instruments will pay the shipping costs of returning to the owner parts which are covered by warranty.

National Instruments believes that the information in this document is accurate. The document has been carefully reviewed for technical accuracy. In the event that technical or typographical errors exist, National Instruments reserves the right to make changes to subsequent editions of this document without prior notice to holders of this edition. The reader should consult National Instruments if errors are suspected. In no event shall National Instruments be liable for any damages arising out of or related to this document or the information contained in it.

EXCEPT AS SPECIFIED HEREIN, NATIONAL INSTRUMENTS MAKES NO WARRANTIES, EXPRESS OR IMPLIED, AND SPECIFICALLY DISCLAIMS ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. CUSTOMER'S RIGHT TO RECOVER DAMAGES CAUSED BY FAULT OR NEGLIGENCE ON THE PART OF NATIONAL INSTRUMENTS SHALL BE LIMITED TO THE AMOUNT THEREFORE PAID BY THE CUSTOMER. NATIONAL INSTRUMENTS WILL NOT BE LIABLE FOR DAMAGES RESULTING FROM LOSS OF DATA, PROFITS, USE OF PRODUCTS, OR INCIDENTAL OR CONSEQUENTIAL DAMAGES, EVEN IF ADVISED OF THE POSSIBILITY THEREOF. This limitation of the liability of National Instruments will apply regardless of the form of action, whether in contract or tort, including negligence. Any action against National Instruments must be brought within one year after the cause of action accrues. National Instruments shall not be liable for any delay in performance due to causes beyond its reasonable control. The warranty provided herein does not cover damages, defects, malfunctions, or service failures caused by owner's failure to follow the National Instruments installation, operation, or maintenance instructions; owner's modification of the product; owner's abuse, misuse, or negligent acts; and power failure or surges, fire, flood, accident, actions of third parties, or other events outside reasonable control.

Copyright

Under the copyright laws, this publication may not be reproduced or transmitted in any form, electronic or mechanical, including photocopying, recording, storing in an information retrieval system, or translating, in whole or in part, without the prior written consent of National Instruments Corporation.

Trademarks

CVI™, DAQCard™, DAQPad™, LabVIEW™, National Instruments™, NI™, ni.com™, NI-DAQ™, RTSI™, and SCXI™ are trademarks of National Instruments Corporation.

FireWire is a trademark of Apple Computer, Inc. Other product and company names mentioned herein are trademarks or trade names of their respective companies.

Patents

For patents covering National Instruments products, refer to the appropriate location: **Help»Patents** in your software, the `patents.txt` file on your CD, or `ni.com/patents`.

WARNING REGARDING USE OF NATIONAL INSTRUMENTS PRODUCTS

(1) NATIONAL INSTRUMENTS PRODUCTS ARE NOT DESIGNED WITH COMPONENTS AND TESTING FOR A LEVEL OF RELIABILITY SUITABLE FOR USE IN OR IN CONNECTION WITH SURGICAL IMPLANTS OR AS CRITICAL COMPONENTS IN ANY LIFE SUPPORT SYSTEMS WHOSE FAILURE TO PERFORM CAN REASONABLY BE EXPECTED TO CAUSE SIGNIFICANT INJURY TO A HUMAN.

(2) IN ANY APPLICATION, INCLUDING THE ABOVE, RELIABILITY OF OPERATION OF THE SOFTWARE PRODUCTS CAN BE IMPAIRED BY ADVERSE FACTORS, INCLUDING BUT NOT LIMITED TO FLUCTUATIONS IN ELECTRICAL POWER SUPPLY, COMPUTER HARDWARE MALFUNCTIONS, COMPUTER OPERATING SYSTEM SOFTWARE FITNESS, FITNESS OF COMPILERS AND DEVELOPMENT SOFTWARE USED TO DEVELOP AN APPLICATION, INSTALLATION ERRORS, SOFTWARE AND HARDWARE COMPATIBILITY PROBLEMS, MALFUNCTIONS OR FAILURES OF ELECTRONIC MONITORING OR CONTROL DEVICES, TRANSIENT FAILURES OF ELECTRONIC SYSTEMS (HARDWARE AND/OR SOFTWARE), UNANTICIPATED USES OR MISUSES, OR ERRORS ON THE PART OF THE USER OR APPLICATIONS DESIGNER (ADVERSE FACTORS SUCH AS THESE ARE HEREAFTER COLLECTIVELY TERMED "SYSTEM FAILURES"). ANY APPLICATION WHERE A SYSTEM FAILURE WOULD CREATE A RISK OF HARM TO PROPERTY OR PERSONS (INCLUDING THE RISK OF BODILY INJURY AND DEATH) SHOULD NOT BE RELIANT SOLELY UPON ONE FORM OF ELECTRONIC SYSTEM DUE TO THE RISK OF SYSTEM FAILURE. TO AVOID DAMAGE, INJURY, OR DEATH, THE USER OR APPLICATION DESIGNER MUST TAKE REASONABLY PRUDENT STEPS TO PROTECT AGAINST SYSTEM FAILURES, INCLUDING BUT NOT LIMITED TO BACK-UP OR SHUT DOWN MECHANISMS. BECAUSE EACH END-USER SYSTEM IS CUSTOMIZED AND DIFFERS FROM NATIONAL INSTRUMENTS' TESTING PLATFORMS AND BECAUSE A USER OR APPLICATION DESIGNER MAY USE NATIONAL INSTRUMENTS PRODUCTS IN COMBINATION WITH OTHER PRODUCTS IN A MANNER NOT EVALUATED OR CONTEMPLATED BY NATIONAL INSTRUMENTS, THE USER OR APPLICATION DESIGNER IS ULTIMATELY RESPONSIBLE FOR VERIFYING AND VALIDATING THE SUITABILITY OF NATIONAL INSTRUMENTS PRODUCTS WHENEVER NATIONAL INSTRUMENTS PRODUCTS ARE INCORPORATED IN A SYSTEM OR APPLICATION, INCLUDING, WITHOUT LIMITATION, THE APPROPRIATE DESIGN, PROCESS AND SAFETY LEVEL OF SUCH SYSTEM OR APPLICATION.

About This Manual

The *Traditional NI-DAQ User Manual* is for users of the Traditional NI-DAQ application programming interface (*API*) of the NI-DAQ software, version 7.0. NI-DAQ is a powerful API between your data acquisition (*DAQ*) application and the National Instruments DAQ devices. This manual includes source code for several example applications.

How to Use the Traditional NI-DAQ Documentation Set

Begin by reading the NI-DAQ 7.0 readme file and the *DAQ Quick Start Guide for NI-DAQ 7.0* for information on how to set up your DAQ system using Traditional NI-DAQ.

Read this manual to learn about programming with Traditional NI-DAQ. When you are familiar with the material in this manual, you can begin to use the Traditional NI-DAQ reference help files for more information on functions and VIs. Other documentation includes *Measurement & Automation Explorer Help for Traditional NI-DAQ*, a help file installed with Measurement & Automation Explorer (MAX).

For detailed hardware information, refer to the user manual included with each device.

Conventions Used in This Manual

The following conventions are used in this manual.

»

The » symbol leads you through nested menu items and dialog box options to a final action. The sequence **File»Page Setup»Options** directs you to pull down the **File** menu, select the **Page Setup** item, and select **Options** from the last dialog box.

This icon denotes a note, which alerts you to important information.

bold

Bold text denotes items that you must select or click in the software, such as menu items and dialog box options. Bold text also denotes parameter names and function prototypes.

italic

Italic text denotes variables, emphasis, a cross reference, or an introduction to a key concept. This font also denotes text that is a placeholder for a word or value that you must supply.

`monospace` Text in this font denotes text or characters that you should enter from the keyboard, sections of code, programming examples, and syntax examples. This font is also used for the proper names of disk drives, paths, directories, programs, subprograms, subroutines, device names, functions, operations, properties, methods, variables, filenames and extensions, and code excerpts.

`monospace bold` Bold text in this font denotes the messages and responses that the computer automatically prints to the screen. This font also emphasizes lines of code that are different from the other examples.

monospace italic Italic text in this font denotes text that is a placeholder for a word or value that you must supply.

MIO and AI Device Terminology

This manual uses generic terms to describe groups of devices whenever possible. The generic terms for the multifunction I/O (MIO) and analog input (AI) devices are based on the number of bits, the platform, and the functionality. The following table lists each MIO and AI device and the technical details for each.

Table 1. MIO and AI Device Technical Details

Device	Number of Single-Ended (SE) Channels	Bit	Type	Functionality
AT-AI-16XE-10	16	16-bit	AT	AI
AT-MIO-16DE-10	16	12-bit	AT	MIO
AT-MIO-16E-1	16	12-bit	AT	MIO
AT-MIO-16E-2	16	12-bit	AT	MIO
AT-MIO-16E-10	16	12-bit	AT	MIO
AT-MIO-16XE-10	16	16-bit	AT	MIO
AT-MIO-16XE-50	16	16-bit	AT	MIO
AT-MIO-64E-3	64	12-bit	AT	MIO
DAQCard-6023E	16	12-bit	PCMCIA	AI
DAQCard-6024E	16	12-bit	PCMCIA	MIO
DAQCard-6062E	16	12-bit	PCMCIA	MIO
DAQPad-6020E	16	12-bit	USB	MIO

Table 1. MIO and AI Device Technical Details (Continued)

Device	Number of Single-Ended (SE) Channels	Bit	Type	Functionality
DAQPad-6052E for FireWire	16	16-bit	FireWire	MIO
DAQPad-6070E for FireWire	16	12-bit	FireWire	MIO
PCI-6013	16	16-bit	PCI	MIO
PCI-6014	16	16-bit	PCI	MIO
PCI-6023E	16	12-bit	PCI	AI
PCI-6024E	16	12-bit	PCI	MIO
PCI-6025E	16	12-bit	PCI	MIO
PCI-6031E (MIO-64XE-10)	64	16-bit	PCI	MIO
PCI-6032E (AI-16XE-10)	16	16-bit	PCI	AI
PCI-6033E (AI-64XE-10)	64	16-bit	PCI	AI
PCI-6034E	16	16-bit	PCI	AI
PCI-6035E	16	16-bit AI, 12-bit AO	PCI	MIO
PCI-6040E (PCI-MIO-16E-4)	16	12-bit	PCI	MIO
PCI-6052E	16	16-bit	PCI	MIO
PCI-6070E (PCI-MIO-16E-1)	16	12-bit	PCI	MIO
PCI-6071E (MIO-64E-1)	64	12-bit	PCI	MIO
PCI-6110	4, DIFF only	12-bit AI, 16-bit AO	PCI	MIO
PCI-6111	2, DIFF only	12-bit AI, 16-bit AO	PCI	MIO
PCI-6115	4, DIFF only	12-bit	PCI	MIO
PCI-6120	4, DIFF only	16-bit	PCI	MIO
PCI-MIO-16XE-10	16	16-bit	PCI	MIO
PCI-MIO-16XE-50	16	16-bit	PCI	MIO
PXI-6025E	16	12-bit	PXI	MIO
PXI-6030E	16	16-bit	PXI	MIO
PXI-6031E	64	16-bit	PXI	MIO

Table 1. MIO and AI Device Technical Details (Continued)

Device	Number of Single-Ended (SE) Channels	Bit	Type	Functionality
PXI-6040E	16	12-bit	PXI	MIO
PXI-6052E	16	16-bit	PXI	MIO
PXI-6070E	16	12-bit	PXI	MIO
PXI-6115	4, DIFF only	12-bit	PXI	MIO
PXI-6120	4, DIFF only	16-bit	PXI	MIO

Introduction to Traditional NI-DAQ

This chapter presents an overview of Traditional NI-DAQ.

About the Traditional NI-DAQ Software

Thank you for buying a National Instruments DAQ device, which includes Traditional NI-DAQ software. Traditional NI-DAQ is a set of functions that control all of the National Instruments plug-in DAQ devices for analog I/O, digital I/O, timing I/O, SCXI signal conditioning, and *RTSI* multiboard synchronization.

Traditional NI-DAQ has both *high-level* DAQ I/O functions for maximum ease of use, and *low-level* DAQ I/O functions for maximum flexibility and performance. Examples of high-level functions are streaming data to disk or acquiring a certain number of data points. Examples of low-level functions are writing directly to the DAQ device registers or calibrating the analog inputs. Traditional NI-DAQ does not sacrifice the performance of National Instruments DAQ devices, because it lets multiple devices operate at their peak performance.

Traditional NI-DAQ includes a *Buffer and Data Manager* that uses sophisticated techniques for handling and managing data acquisition buffers, so you can acquire and process data simultaneously. Traditional NI-DAQ can transfer data using *DMA*, *interrupts*, or software polling. Traditional NI-DAQ can use DMA to transfer data into memory above 16 *MB*, even on ISA bus computers.

With the *Resource Manager*, you can use several functions and several devices simultaneously. The Resource Manager prevents multiboard contention over DMA channels, interrupt levels, and *RTSI* channels.

Traditional NI-DAQ can send *event-driven messages* to Windows or Windows NT applications each time a user-specified event occurs. Thus, polling is eliminated and you can develop event-driven DAQ applications. Some examples of Traditional NI-DAQ user events are:

- When a specified number of analog samples has been acquired
- When the analog level and slope of a signal match specified levels
- When the signal is inside or outside a voltage band
- When a specified digital I/O pattern is matched
- When a rising or falling edge occurred on a timing I/O line

How to Set Up Your DAQ System

Refer to the *DAQ Quick Start Guide for NI-DAQ 7.0* for more information on installing and configuring your hardware and software.

Traditional NI-DAQ Overview

Traditional NI-DAQ is a library of routines that work with National Instruments DAQ devices. Traditional NI-DAQ helps you perform tasks ranging from simple device initialization to advanced high-speed data logging. The number of tasks you need for your applications depends on the types of DAQ devices you have and the complexity of your applications.

Device Configuration

Before you begin your Traditional NI-DAQ application development, you must configure your National Instruments DAQ devices. Traditional NI-DAQ needs the device configuration information to program your hardware correctly.

Using Measurement & Automation Explorer

Measurement & Automation Explorer (MAX) is a Windows-based application that you use to configure and view National Instruments DAQ device settings under Windows 2000/NT/XP/Me/98.

Note To use MAX, quit any applications that are performing DAQ operations.

Double-click the **Measurement & Automation** icon on your desktop to run MAX. Refer to the *Measurement & Automation Explorer Help for Traditional NI-DAQ* for more information and detailed instructions on configuring your devices and accessories.

Fundamentals of Building Windows Applications

This chapter describes the fundamentals of creating Traditional NI-DAQ applications in Windows 2000/NT/XP/Me/98.

The following section contains general information about building Traditional NI-DAQ applications, describes the nature of the Traditional NI-DAQ files used in building Traditional NI-DAQ applications, and explains the basics of making applications using the following tools:

- Microsoft Visual C++
- Microsoft Visual Basic

If you are not using the tools listed, refer to your development tool reference manual for details on creating applications that call [DLLs](#).

The Traditional NI-DAQ Libraries

The Traditional NI-DAQ function libraries are DLLs, which means that Traditional NI-DAQ routines are not linked into the executable files of applications. Only the information about the Traditional NI-DAQ routines in the Traditional NI-DAQ import libraries is stored in the executable files.

Note Use the 32-bit `nidaq32.dll`. If you are programming in C or C++, link in the appropriate import library. Refer to the following sections for language-specific details.

Using function prototypes is a good programming practice. That is why Traditional NI-DAQ is packaged with function prototype files for different Windows development tools. The installation utility copies the appropriate prototype files for the development tools you choose. If you are not using any of the development tools that Traditional NI-DAQ works with, you must create your own function prototype file.

Creating a Windows Application Using Microsoft Visual C++

This section assumes that you will be using the Microsoft Visual C++ IDE to manage your code development, and that you are familiar with the IDE.

Developing a Traditional NI-DAQ Application

To develop a Traditional NI-DAQ application, follow these general steps:

1. Open an existing or new Visual C++ project to manage your application code.
2. Create files of type `.c` (C source code) or `.cpp` (C++ source code) and add them to the project. Make sure you include the Traditional NI-DAQ header file, `nidaq.h`, as such in your source code files:

```
#include "nidaq.h"
```

You also might want to include `nidaqcns.h` and `nidaqerr.h`. You also can include other files (for example, `.rc`, `.def`) that you have created for graphical user interface (GUI) applications.

3. Specify the directory which contains the Traditional NI-DAQ header files under the **preprocessor>include directory** settings in your compiler. (For Visual C++ 4.x, this is under **Build>Settings>C/C++**. For Visual C++ 5.0/6.0, this is under **Project>Settings>C/C++**.) The Traditional NI-DAQ header files are located in the `.\Include` directory under your NI-DAQ directory.
4. Add the Traditional NI-DAQ import library `nidaq32.lib` to the project. The Traditional NI-DAQ import library files are located in the `.\Lib` directory under your NI-DAQ directory.
5. Build your application.

Example Programs

You can find example programs and project files in `.\Examples\VisualC` directory under your NI-DAQ directory.

To load an example program, use one of the generic makefiles with the `.mak` extension.

To load an example project with Visual C++ 4.x or later, select the menu option **File>Open Project Workspace**, and select **List Files of Type** to be **Makefiles**. Then select the `.mak` file of your choice.

Special Considerations

When developing an application using Visual C++, consider the following special considerations.

Buffer Allocation

To allocate memory, you can use the Windows API function `GlobalAlloc()`. After allocation, lock memory with `GlobalLock()` to use a buffer of memory. You can use the memory handle returned by `GlobalLock()` in place of the **buffer** parameter in Traditional NI-DAQ API functions that accept buffers (`Align_DMA_Buffer`, `DAQ_DB_Transfer`, `DAQ_Monitor`, `DAQ_Op`, `DAQ_Start`, `DIG_Block_In`, `DIG_Block_Out`, `DIG_DB_Transfer`, `GPCTR_Config_Buffer`, `GPCTR_Read_Buffer`, `Lab_ISCAN_Op`, `Lab_ISCAN_Start`, `SCAN_Op`, `SCAN_Start`, `SCAN_Sequence_Demux`, `WFM_DB_Transfer`, `WFM_Load`, `WFM_Op`). After using the memory, unlock memory with `GlobalUnlock()` and free it with `GlobalFree()`.

Note If you allocate memory from `GlobalAlloc()`, you must call `GlobalLock()` on the memory object before passing it to Traditional NI-DAQ.

String Passing

To pass strings, pass a pointer to the first element of the character array. Be sure that the string is null-terminated.

Parameter Passing

By default, C passes parameters by value. Remember to pass pointers to variables when you need to pass by address.

Creating a Windows Application Using Microsoft Visual Basic

This section assumes that you will be using the Microsoft Visual Basic IDE to manage your code development, and that you are familiar with the IDE.

Developing a Traditional NI-DAQ Application

To develop a Traditional NI-DAQ application, follow these general steps:

1. Open an existing or new Visual Basic project to manage your application code.
2. Create files of type `.frm` (form definition and event handling code), `.bas` (Visual Basic generic code module), or `.cls` (Visual Basic class module) and add them to the project.
3. Include the Traditional NI-DAQ include file for Visual Basic, `nidaq32.bas`, into your project. You also might want to include `nidaqcns.inc` and `nidaqerr.inc`. The Traditional NI-DAQ include files for Visual Basic are located in the `.\Include` directory under your NI-DAQ directory. For Visual Basic 5.0/6.0, you can select the **Project»Add Module** menu option, click the **Existing** tab, and select the module of your choice.

Alternatively, you can add a reference to the National Instruments Data Acquisition Type Library, which is part of the Traditional NI-DAQ DLL. In Visual Basic 5.0/6.0, select the **Project»References** menu option, and check **National Instruments Data Acquisition Library**. If you do not see it listed there, click the **Browse** button and locate `nidaq32.dll` in your `\Windows\system` or `\Windows\system32` directory.

4. Run your application by clicking the **Run** button.

Note In Visual Basic, function declarations have scope globally throughout the project. In other words, you can define your prototypes in any module. The functions will be recognized even in other modules.

For information on using the NI-DAQ Visual Basic Custom Controls, refer to the [Traditional NI-DAQ Events in Visual Basic](#) section of Chapter 3, [Software Overview](#).

Refer to the Traditional NI-DAQ reference help files for more information on using the Traditional NI-DAQ functions in Visual Basic for Windows.

Example Programs

You can find example programs and project files in the `.\Examples\VBASIC` directory under your Traditional NI-DAQ directory.

To load an example program, use one of the Visual Basic project files with the `.vbp` extension. These are Visual Basic 4.0 projects, which you can open only with Visual Basic version 4.0 or later.

To load an example project with Visual Basic 4.0 or later versions, select the menu option **File»Open Project**, then select the .vbp file of your choice.

Special Considerations

When developing an application using Visual Basic, consider the following special considerations.

Buffer Allocation

Visual Basic 4.0 is restrictive when allocating memory. You allocate memory by declaring an array of the data type with which you want to work. Visual Basic uses dynamic memory allocation so you can redimension an array to a variable size during run time. However, arrays are restricted to being less than 64 KB in *total* size (this translates to about 32,767 (16-bit) integers, 16,384 (32-bit) long integers, or 8,191 doubles).

To break the 64 KB buffer size barrier, you can use the Windows API functions `GlobalAlloc()` to allocate buffers larger than 64 KB. After allocation, you must lock memory with `GlobalLock()` to use a buffer of memory. You can use the memory handle returned by `GlobalLock()` in place of the buffer parameter in Traditional NI-DAQ API functions that accept buffers (`Align_DMA_Buffer`, `DAQ_DB_Transfer`, `DAQ_Monitor`, `DAQ_Op`, `DAQ_Start`, `DIG_Block_In`, `DIG_Block_Out`, `DIG_DB_Transfer`, `GPCTR_Config_Buffer`, `GPCTR_Read_Buffer`, `Lab_ISCAN_Op`, `Lab_ISCAN_Start`, `SCAN_Op`, `SCAN_Start`, `SCAN_Sequence_Demux`, `WFM_DB_Transfer`, `WFM_Load`, `WFM_Op`). The Traditional NI-DAQ header file declares the buffer parameter “As Any.” After using the memory, you must unlock memory with `GlobalUnlock()` and free it with `GlobalFree()`.

Note If you allocate memory from `GlobalAlloc()`, you must call `GlobalLock` on the memory object before passing it to Traditional NI-DAQ.

The following paragraph illustrates declarations of functions.

For Visual Basic 4.0 or later, 32-bit:

```
Declare Function GlobalAlloc Lib "kernel32" Alias
"GlobalAlloc" (ByVal wFlags As Long, ByVal dwBytes As
Long) As Long
```

```
Declare Function GlobalFree Lib "kernel32" Alias
"GlobalFree" (ByVal hMem As Long) As Long
```

```

Declare Function GlobalLock Lib "kernel32" Alias
"GlobalLock" (ByVal hMem As Long) As Long

Declare Function GlobalReAlloc Lib "kernel32" Alias
"GlobalReAlloc" (ByVal hMem As Long, ByVal dwBytes As
Long, ByVal wFlags As Long) As Long

Declare Function GlobalUnlock Lib "kernel32" Alias
"GlobalUnlock" (ByVal hMem As Long) As Long

```

String Passing

In Visual Basic, variables of data type `String` need no special modifications to be passed to Traditional NI-DAQ functions. Visual Basic automatically appends a null character to the end of a string before passing it (by reference, because strings cannot be passed by value in Visual Basic) to a procedure or function.

Parameter Passing

By default, Visual Basic passes parameters by reference. Prepend the `ByVal` keyword if you need to pass by value.

Passing Unsigned 16-Bit and 32-Bit Integer Parameters

The Visual Basic `INTEGER` type is a signed value. Visual Basic considers any value greater than 32,767 a negative number. To pass unsigned 16-bit parameters, refer to the following examples:

- If the function is supposed to return an unsigned 16-bit integer, and you are reading back a negative number, add 65,536 to the negative number.

```

Dim myUnsignedCnt As Long
Dim retCnt As Integer

'retCnt is the value returned from the called
'function.

'You can call a DAQ function that returns an unsigned
'16-bit value and store the value in retCnt.

if retCnt < 0 then
    myUnsignedCnt = CInt(retCnt) + 65536
else
    myUnsignedCnt = retCnt
end if

```

- To pass an unsigned 16-bit value to a function with an unsigned 16-bit type parameter, you must first compute the value to pass to the function.

```
Dim myUnsignedCnt As Long
Dim ToPassVal As Integer

'You compute the value that you want to pass to the
'function and store it in myUnsignedCnt.
if myUnsignedCnt > 32767 then
    ToPassVal = CInt(myUnsignedCnt - 65536)
else
    ToPassVal = CInt(myUnsignedCnt)
end if
```

The Visual Basic LONG integer type is a signed 32-bit type. Visual Basic considers any value greater than 2,147,483,647 a negative number. To pass unsigned 16-bit parameters, refer to the following examples:

- If the function is supposed to return an unsigned 32-bit integer, and you are reading back a negative number, then add 4,294,967,296 to the negative number.

```
Dim myUnsignedCnt As Double
Dim retCnt As Long

'retCnt is the value returned from the called
'function
'You can call a DAQ function that returns an unsigned
'16-bit value and stores it in retCnt.
if retCnt < 0 then
    myUnsignedCnt = CInt(retCnt) + 4294967296
else
    myUnsignedCnt = retCnt
end if
```

- To pass an unsigned 32-bit value to a function with an unsigned 32-bit type parameter, you must first compute the value to pass to the function.

```
Dim myUnsignedCnt As Double
Dim ToPassVal As Long

'You compute the value that you want to pass to the
'function and store it in myUnsignedCnt.
```

```

if myUnsignedCnt > 2147483647 then
    ToPassVal = CLng(myUnsignedCnt - 4294967296)
else
    ToPassVal = CLng(myUnsignedCnt)
end if

```

Traditional NI-DAQ Examples

The Traditional NI-DAQ installer installs a suite of concisely written examples in the following application development environments:

- LabWindows™/CVI™ 5.0.x
- Microsoft Visual C++ 2.x (32-bit) or later
- Microsoft Visual Basic 4.0 (32-bit) or later

These examples illustrate how to use Traditional NI-DAQ functions to perform a single task. All examples are devoid of any code to extract values from GUI objects so that you can focus on how the code flow is formed. In addition, most parameters are hardcoded at the top of the routine so that if you decide to change them, you can simply change the assignment.

The examples correspond to the function flowcharts that you will see in Chapter 3, *Software Overview*. If a task and a flowchart in the following chapter suits your data acquisition needs, you should find a corresponding example to get you started.

Each example consists of the following files:

- An appropriate project file for the programming language
- A single source code file to illustrate the task at hand
- A library of Traditional NI-DAQ example utility functions (for buffer creation, waveform plotting, error checking, and implementing a delay)

Note None of the examples are installed in their executable (.exe) format. To run them, you first must build them or load them into the IDE for the appropriate programming language.

The examples are stored in the hierarchy shown below for each language:

```

.\AI           Analog Input examples
.\AO           Analog Output examples

```

. \DI	Digital Input examples
. \DO	Digital Output examples
. \CTR	Counter/timer examples
. \SCXI	SCXI examples
. \CALIB	Calibration examples

The project files have the same file name (not including extension) as the source code files. The following types are installed:

- LabWindows/CVI:
 - .prj (project file), .c (source file)
- Visual C++:
 - .mak (generic make file), .c (source file)
- Visual Basic:
 - .vbp (project file, for Visual Basic 4.0 [32-bit] or later),
 - .frm (form module)

Software Overview

This chapter describes the function classes in Traditional NI-DAQ and briefly describes each function.

Traditional NI-DAQ functions are grouped according to the following classes:

- Initialization and general-configuration
- Software-calibration and device-specific
- Event Message
- Analog input function group
 - One-shot analog input
 - Single-channel analog input
 - Data acquisition
 - High-level data acquisition
 - Low-level data acquisition
 - Low-level double-buffered data acquisition
- Analog output function group
 - One-shot analog output
 - Waveform generation
 - High-level waveform generation
 - Low-level waveform generation
- Digital I/O function group
 - Digital I/O
 - Group digital I/O
 - Double-buffered digital I/O
 - Change Notification
 - Filtering

- Counter/Timer function group
 - Counter/timer
 - Interval [counter/timer](#)
 - General-purpose counter/timer
- RTSI bus trigger
- SCXI
- Transducer conversion

Initialization and General-Configuration Functions

Use these general functions for initializing and configuring your hardware and software.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

<code>Align_DMA_Buffer</code>	Aligns the data in a DMA buffer to avoid crossing a physical page boundary. This function is for use with DMA waveform generation and digital I/O pattern generation.
<code>Get_DAQ_Device_Info</code>	Retrieves parameters pertaining to the device operation.
<code>Get_NI_DAQ_Version</code>	Returns the version number of the Traditional NI-DAQ library.
<code>Init_DA_Brds</code>	Initializes the hardware and software states of a National Instruments DAQ device to its default state and then returns a numeric device code that corresponds to the type of device initialized. Any operation that the device is performing is halted. Traditional NI-DAQ automatically calls this function; your application does not have to call it explicitly. This function is useful for reinitializing the device hardware, for reinitializing the Traditional NI-DAQ software, and for determining which

device has been assigned to a particular slot number.

`Set_DAQ_Device_Info`

Selects parameters pertaining to the device operation.

`Timeout_Config`

Establishes a timeout limit that is used by the synchronous functions to ensure that these functions eventually return control to your application. Examples of synchronous functions are `DAQ_Op`, `DAQ_DB_Transfer`, and `WFM_from_Disk`.

Software-Calibration and Device-Specific Functions

Each of these software-calibration and configuration functions is specific to only one type of device or class of devices.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

`AO_Calibrate`

Loads a set of calibration constants into the calibration *DACs* or copies a set of calibration constants from one of four *EEPROM* areas to EEPROM area 1. You can load an existing set of calibration constants into the calibration DACs from a storage area in the onboard EEPROM. You can copy EEPROM storage areas 2 through 5 (EEPROM area 5 contains the factory-calibration constants) to storage area 1. NI-DAQ automatically loads the calibration constants stored in EEPROM area 1 the first time a function pertaining to the AT-AO-6/10 is called.

`Calibrate_1200`

Calibrates the *gain* and offset values for the 1200/AI devices *ADCs* and DACs. You can perform a new calibration or use an existing set of calibration constants by copying the constants from their storage location in the onboard EEPROM. You

	can store up to six sets of calibration constants. Traditional NI-DAQ automatically loads the calibration constants stored in EEPROM user area 5 the first time you call a function pertaining to the device.
<code>Calibrate_TIO</code>	Use the function to calibrate the crystal oscillator on your timing I/O 660X device.
<code>Calibrate_DSA</code>	Use this function to calibrate your DSA device.
<code>Calibrate_E_Series</code>	Use this function to calibrate your E Series, 671X, or 673X device and to select a set of calibration constants for Traditional NI-DAQ to use.
<code>Configure_HW_Analog_Trigger</code>	Configures the hardware <i>analog trigger</i> available on your E Series device.
<code>LPM16_Calibrate</code>	Calibrates the LPM device converter. The function calculates the correct offset voltage for the voltage comparator, adjusts positive linearity and full-scale errors to less than ± 0.5 each, and adjusts zero error to less than ± 1 LSB.
<code>MIO_Config</code>	Turns <i>dithering</i> on and off. For the MIO-64, this function also lets you specify whether to use AMUX-64T channels or onboard channels.
<code>SCXI_Calibrate</code>	Performs a self-calibration (or internal calibration) for certain SCXI modules.
<code>Select_Signal</code>	Selects the source and polarity of certain signals used by the E Series and DSA devices. You typically need to use this function to externally control timing, to use the RTSI bus, or to configure one of the I/O connector PFI pins.

Event Message Functions

Traditional NI-DAQ Event Message functions are an efficient way to monitor your background data acquisition processes, without dedicating your foreground process for status checking.

The Event Message dispatcher notifies your application when a user-specified DAQ event occurs. Using event messaging eliminates continuous polling of data acquisition processes.

`Config_Alarm_Deadband` Specify alarm on/off condition for data acquisition event messaging.

`Config_ATrig_Event_Message` Specify analog input trigger level and slope for data acquisition event messaging.

`Config_DAQ_Event_Message` Specify analog input, analog output, digital input, or digital output trigger condition for event messaging.

Event Messaging Application Tips

To receive notification from the Traditional NI-DAQ data acquisition process in case of special events, you can call `Config_Alarm_Deadband`, `Config_ATrig_Event_Message`, or `Config_DAQ_Event_Message` to specify an event in which you are interested. If you are interested in more than one event, you can call any of those three functions again for each event.

After you have configured all event messages, you can begin your data acquisition by calling `SCAN_Start`, `DIG_Block_In`, and so on.

When any of the events you specified occur, Traditional NI-DAQ notifies your application.

Event notification can be done through user-defined callbacks and/or the Windows Message queue. When a user-specified event occurs, Traditional NI-DAQ calls the user-defined callback (if defined) and/or puts a message into the Windows Message queue, if you specified a window handle. Your application receives the message when it calls the Windows `GetMessage` API.

After your application receives an event message, it can carry out the appropriate task, such as updating the screen or saving data to disk.

To restart your data acquisition process after it completes, you do not need to call the message configuration calls again. They remain defined as long as your application does not explicitly remove them or call `Init_DA_Brds`.

To add or remove a message, first clear your data acquisition process. Then, call one of the three event message configuration functions.

Traditional NI-DAQ Events in Visual Basic

ActiveX Controls for Visual Basic

Unlike standard control-flow programming languages, event occurrences drive Visual Basic code. You interact with outside events through the properties and procedures of a control. For any given control, there is a set of procedures called *event procedures* that affect that control.

For example, a command button named **Run** has a procedure called `Run_Click()` that is called when you click the **Run** button. If you want something to run when you click the **Run** button, enter code in the `Run_Click()` procedure. When a program starts executing, Visual Basic looks for events related to controls and calls control procedures as necessary. You do not write an event loop.

There are three Traditional NI-DAQ ActiveX controls for Visual Basic applications:

- General Data Acquisition Event (`dagevent.ocx`)

- Analog Trigger Event (`atrigev.ocx`)

- Analog Alarm Event (`alarmev.ocx`)

The Traditional NI-DAQ installer places all of these ActiveX controls in the NIDAQ subdirectory of your Windows 2000/NT/XP/Me/98 directory under the file names shown.

These three ActiveX controls actually call the Traditional NI-DAQ `Config_DAQ_Event_Message`, `Config_ATrig_Event_Message`, and `Config_Alarm_Deadband` functions. Visual Basic applications cannot receive Windows messages, but if you use Traditional NI-DAQ ActiveX controls shown previously in this section, your Visual Basic application can receive Traditional NI-DAQ messages.

Note You can use the *OCXs* in Visual Basic, version 4.0 (32-bit) or later.

General DAQ Event

You use the General DAQ Event control to configure and enable a single data acquisition event. Refer to the *Event Message Functions* section for a complete description of Traditional NI-DAQ events. Table 3-1 lists the properties for the General DAQ Event control.

Note An *n* represents a generic number and is not the same value in every occurrence.

Table 3-1. General DAQ Event Control Properties

Property	Allowed Property Values
Name	GeneralDAQEvent <i>n</i> (default)
Board	1 – <i>n</i> (default)
ChanStr	Refer to <code>Config_DAQ_Event_Message</code> in the <i>Traditional NI-DAQ C Reference Help</i> .
DAQEvent	0—Acquired or generated <i>n</i> scans 1—Every <i>n</i> scans 2—Completed operation or stopped by error 3—Voltage out of bounds 4—Voltage within bounds 5—Analog positive slope triggering 6—Analog negative slope triggering 7—Digital pattern not matched 8—Digital pattern matched 9—Counter pulse event
DAQTrigVal0	Long

Table 3-1. General DAQ Event Control Properties (Continued)

Property	Allowed Property Values
DAQTrigVal1	Long
TrigSkipCount	Long
PreTrigScans	Long
PostTrigScans	Long
Index	N/A
Tag	N/A
Enabled	0—False (default) 1—True

Some General DAQ Events can be implemented only by a select group of National Instruments DAQ devices. Also, some General DAQ Events require that you set the *asynchronous* data acquisition or generation operation to use interrupts. For more information on the different types of General DAQ Events, refer to the description for the `Config_DAQ_Event_Message` function in the *Traditional NI-DAQ C Reference Help*.

Set each of these properties as follows:

```
GeneralDAQEventn.property name = property value
```

For example, to set the `ChanStr` property to Analog Input channel 0 for GeneralDAQEvent 1:

```
GeneralDAQEvent1.ChanStr = "AI0"
```

Set up your program flow like this:

1. Set the properties of the General DAQ Event control. Then, configure the acquisition or generation operations using the appropriate Traditional NI-DAQ functions.
2. Set the `Enabled` property of the General DAQ Event control to 1 (True).
3. Invoke the `GeneralDAQEventn.Refresh` method to set the DAQ Event in the Traditional NI-DAQ driver. Each subsequent use of `GeneralDAQEventn.Refresh` deletes the old DAQ Event and sets a new one with the current set of properties.
4. Start an *asynchronous* data acquisition or generation operation.

- When the selected event occurs, the `GeneralDAQEventn_Fire` procedure is called. You can perform the necessary event processing within this procedure, such as updating a global count variable, or toggling digital I/O lines.

The `GeneralDAQEventn_Fire` procedure is prototyped as follows:

Sub GeneralDAQEventn_Fire (DoneFlag As Integer, Scans As Long)

The parameter **DoneFlag** equals 1 if the acquisition was over when the DAQ Event fired. Otherwise, it is 0. **Scans** equals the number of the scan that caused the DAQ Event to fire.

For a detailed example of how to use the General DAQ Event control in a Visual Basic program, refer to the General DAQ Event example at the end of the *Traditional NI-DAQ Events in Visual Basic* section.

Analog Trigger Event

Use the Analog Trigger Event control to configure and enable an *analog trigger*. Refer to the *Event Message Functions* section earlier in this chapter for a definition of the analog trigger.

Table 3-2 lists the properties for the Analog Trigger Event control.

Table 3-2. Analog Trigger Event Control Properties

Property	Allowed Property Values
Name	GeneralDAQEventn (default)
Board	1 – n (default)
ChanStr	Refer to <code>Config_DAQ_Event_Message</code> in the <i>Traditional NI-DAQ C Reference Help</i>
Level	Single (voltage)
WindowSize	Single (voltage)
Slope	0—Positive (default) 1—Negative
TrigSkipCount	Long
PreTrigScans	Long
PostTrigScans	Long

Table 3-2. Analog Trigger Event Control Properties (Continued)

Property	Allowed Property Values
Index	N/A
Tag	N/A
Enabled	0—False (default) 1—True

The Analog Trigger Event requires that you set the asynchronous data acquisition operation to use interrupts. For more information on Analog Trigger Events, refer to the descriptions for the `Config_ATrig_Event_Message` function in the *Traditional NI-DAQ C Reference Help*.

Each of these properties should be set as follows:

```
AnalogTriggerEventn.property name = property value
```

For example, to set the `ChanStr` property to Analog Input channel 0 for Analog Trigger Event 1:

```
AnalogTriggerEvent1.ChanStr = "AI0"
```

Set up your program flow like this:

1. Set the properties of the Analog Trigger Event control. Next, configure the acquisition or generation operations using the appropriate Traditional NI-DAQ functions.
2. Set the `Enabled` property of the Analog Trigger Event control to 1 (True).
3. Invoke the `AnalogTriggerEventn.Refresh` method to actually set the Analog Trigger Event in the Traditional NI-DAQ driver. Each subsequent invocation of `AnalogTriggerEventn.Refresh` deletes the old Analog Trigger Event and sets a new one with the current set of properties.
4. Start an asynchronous data acquisition operation.
5. When the Analog Trigger conditions are met, the `AnalogTriggerEventn.Fire` procedure is called. You can perform the necessary event processing within this procedure, such as updating a global count variable, or toggling digital I/O lines.

The `AnalogTriggerEventn_Fire` procedure is prototyped as follows:

**Sub AnalogTriggerEventn_Fire (DoneFlag As Integer,
Scans As Long)**

The parameter **DoneFlag** equals 1 if the acquisition was over when the Analog Trigger Event fired. Otherwise, it is 0. **Scans** equals the number of the scan that caused the Analog Trigger Event to fire.

Analog Alarm Event

Use the Analog Alarm Event control to configure and enable an analog trigger. Refer to the [Event Message Functions](#) section earlier in this chapter for a definition of the analog trigger.

Table 3-3 lists the properties for the Analog Alarm Event control.

Table 3-3. Analog Alarm Event Control Properties

Property	Allowed Property Values
Name	GeneralDAQEventn (default)
Board	1 – n (default)
ChanStr	Refer to <code>Config_DAQ_Event_Message</code> in the <i>Traditional NI-DAQ C Reference Help</i>
HighAlarmLevel	Single (voltage)
LowAlarmLevel	Single (voltage)
HighDeadbandWidth	Single (voltage)
LowDeadbandWidth	Single (voltage)
Index	N/A
Tag	N/A
Enabled	0—False (default) 1—True

The Analog Alarm Event requires that you set the asynchronous data acquisition operation to use interrupts. For more information on Analog Alarm Events, refer to the description for the `Config_Alarm_Deadband` function in the *Traditional NI-DAQ C Reference Help*.

Each of these properties should be set as follows:

AnalogAlarmEventn.property name = property value

For instance, to set the `ChanStr` property to Analog Input channel 0 for Analog Alarm Event 1:

`AnalogAlarmEvent1.ChanStr = "AI0"`

Set up your program flow like this:

1. Set the properties of the Analog Alarm Event control. Next, configure the acquisition or generation operations using the appropriate Traditional NI-DAQ functions.
2. Set the `Enabled` property of the Analog Alarm Event control to 1 (True).
3. Invoke the `AnalogAlarmEventn.Refresh` method to set the Analog Alarm Event in the Traditional NI-DAQ driver. Each subsequent invocation of `AnalogAlarmEventn.Refresh` deletes the old Analog Alarm Event and sets a new one with the current set of properties.
4. Start an asynchronous data acquisition operation.
5. Call any one of the four following procedures:
 - `AnalogAlarm_HighAlarmOn`
 - `AnalogAlarm_HighAlarmOff`
 - `AnalogAlarm_LowAlarmOn`
 - `AnalogAlarm_LowAlarmOff`

You can perform necessary event processing within this procedure, such as updating a global count variable or toggling digital I/O lines.

The four Analog Alarm procedures are prototyped as follows:

**Sub AnalogAlarmn_HighAlarmOn (DoneFlag As Integer,
Scans As Long)**

**Sub AnalogAlarmn_HighAlarmOff (DoneFlag As Integer,
Scans As Long)**

**Sub AnalogAlarmn_LowAlarmOn (DoneFlag As Integer,
Scans As Long)**

**Sub AnalogAlarmn_LowAlarmOff (DoneFlag As Integer,
Scans As Long)**

The parameter **DoneFlag** equals 1 if the acquisition was over when the Analog Alarm Event fired. Otherwise, it is 0. **Scans** equals the number of the scan that caused the Analog Alarm Event to fire.

Using Multiple Controls

In general, a program might contain any number of General DAQ Event, Analog Trigger Event, and Analog Alarm Event controls. Just like regular Visual Basic controls, there are two ways you can place multiple controls on a Visual Basic form:

- You can create control arrays by copying and pasting a control that already exists on the form. Each individual element in the control array is then distinguished by the `Index` property, and the event procedures is an extra parameter `Index as Integer`. The first element has `Index = 0`, the second element has `Index = 1`, and so on. You have only one procedure for each type of event custom control; however, you can determine which control array element caused the event to occur by examining the `Index` property.
- You can place multiple controls from the **Visual Basic Tool Box** onto the form. Each individual custom control of the same type is then distinguished by the number after the name of the custom control, such as `GeneralDAQEvent1`, `GeneralDAQEvent2`, and so on. Consequently, you can have separate procedures for each custom control, such as `GeneralDAQEvent1_Fire`, `GeneralDAQEvent2_Fire`, and so on.

General DAQ Event Example

The following steps provide an outline of how to use the General DAQ Event control in a Visual Basic program. A working knowledge of Visual Basic is assumed; otherwise, this example is complete, except for error checking:

1. To use the `GeneralDAQEvent` control, you must first include the proper control into your project.
 - If you are using Visual Basic 4.0 (32-bit), select the **Tools» Custom Controls** option, and select the **National Instruments GeneralDAQEvent** custom control.
 - If you are using Visual Basic 5.0, select the **Project» Components** option, and select the **National Instruments GeneralDAQEvent** custom control. In either version, if you do not find the custom control listed, click the **Browse** button and find the custom control in the NI-DAQ subdirectory under your Windows directory.

2. To place the GeneralDAQEvent control into your form, go to the tool box window and select the GeneralDAQEvent tool, labelled *DAQ EVENT*.
3. Click somewhere on the form, and while holding down the mouse button, drag the mouse to place the control onto the form. You will see a small icon, which does not appear in run time.
4. To set up a DAQ Event that notifies you after every n scans (DAQ Event #1), unless you decide to make n very large, you can use the Set_DAQ_Device_Info function to set the device analog inputs to use interrupts. The constants used in this function come from NIDAQCNS.INC. Refer to the function description for Set_DAQ_Device_Info in the *Traditional NI-DAQ C Reference Help* for more information. You also must configure some parameters so that the GeneralDAQEvent can occur when it needs to. In the Form_Load event routine, add the following to the existing code:

```
er% = Set_DAQ_Device_Info(1, ND_DATA_XFER_MODE_AI,
ND_INTERRUPTS) set AI to use INTR

GeneralDAQEvent1.Board = 1 'assume Device 1
GeneralDAQEvent1.DAQEvent = 1 'event every N scans
GeneralDAQEvent1.DAQTrigVal0 = 1000 'set N=1000
scans

GeneralDAQEvent1.Enabled = True
```

5. Next, start an asynchronous operation. Use the Traditional NI-DAQ function DAQ_Start. Set up your program so it does a DAQ_Start on channel 0 when you click a button you have placed on your form. To do so, add the following code in the Command1_Click() subroutine as follows:

```
Redim buffer%(10000)

GeneralDAQEvent1.ChanStr = "AI0"

GeneralDAQEvent1.Refresh 'refresh to set params

er% = DAQ_Start(1, 0, 1, buffer%(0), 10000, 3, 10)
```

6. Next, define what to do when the DAQ Event occurs. In this example, we can easily update a text box upon every 1,000 scans and also when the whole acquisition is complete. Place a text box on your form. It is automatically named *Text 1*.
7. Go to the code window, pull down on the **Object** combo box, and select **GeneralDAQEvent1**. The only **Proc** for this control object is **Fire**. Within the subroutine, enter the following code:

```
If (DoneFlag% <> 1) Then
```

```
Text1.Text = Str$(Scans&)+"scans have been
acquired."
```

```
Else
```

```
Text1.Text = "Acquisition is complete!"
```

```
er% = DAQ_Clear(1)
```

```
End If
```

8. Make sure that you stop any ongoing acquisition when you stop the program. To do so, call the `DAQ_Clear` function before the `End` statement in the subroutine `Command2_Click(_)`. Place another button on your form and label it `Exit`. The subroutine should have code as follows:

```
er% = DAQ_Clear(1)
```

```
End
```

9. Run the program. Because you are not going to display the data onto a graph, it does not matter what the data is; however, when you click the **Click Me!** button, the text box should update its contents every second. After all the scans are acquired, you should see the text box display a completion message. If you run into errors, refer to the *Traditional NI-DAQ C Reference Help* for guidance.
10. Click the **Exit** button to stop the program.

Analog Input Function Group

The analog input function group contains two sets of functions—the one-shot analog input functions, which perform single *A/D* conversions, and the data acquisition functions, which perform multiple clocked, buffered A/D functions. Within the analog input functions, single-channel analog input (AI) functions perform single A/D conversions on one channel. Within the data acquisition functions, there are high-level, low-level, and low-level double buffered functions.

If you are using SCXI analog input modules, you must use the SCXI functions first to program the SCXI hardware. Then you can use these functions to acquire the data using your DAQ device.

One-Shot Analog Input Functions

Single-Channel Analog Input Functions

Use the single-channel analog input functions on the MIO and AI devices.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

<code>AI_Check</code>	Returns the status of the analog input circuitry and an analog input reading if one is available. <code>AI_Check</code> is intended for use when A/D conversions are initiated by external pulses applied at the appropriate pin; refer to <code>DAQ_Config</code> in the <i>Traditional NI-DAQ C Reference Help</i> for information on enabling external conversions.
<code>AI_Clear</code>	Clears the analog input circuitry and empties the <i>FIFO</i> memory.
<code>AI_Change_Parameter</code>	Selects a specific parameter setting for the analog input section or analog input channel. Use this to set the <i>coupling</i> for AI channels.
<code>AI_Configure</code>	<p> Informs Traditional NI-DAQ of the input mode (single-ended or differential), input range, and input polarity selected for the device. Use this function if you change the jumpers affecting the analog input configuration from their factory settings. For the E Series devices which have no jumpers for analog input configuration, this function programs the device for the settings you want. For the E Series devices you can configure the input mode and polarity on a per channel basis. Also use <code>AI_Configure</code> to specify whether to drive AISENSE to onboard ground. </p>
<code>AI_Mux_Config</code>	Configures the number of multiplexer (AMUX-64T) devices connected to an MIO and AI device and informs

	Traditional NI-DAQ if any AMUX-64T devices are attached to the system. This function applies <i>only</i> to the MIO and AI devices.
<code>AI_Read</code>	Reads an analog input channel (initiates an A/D conversion on an analog input channel) and returns the unscaled result.
<code>AI_Read_Scan</code>	Returns readings for all analog input channels selected by <code>Scan_Setup</code> .
<code>AI_Read_VScan</code>	Returns readings in volts for analog input channels selected by <code>Scan_Setup</code> .
<code>AI_Setup</code>	Selects the specified analog input channel and gain setting for externally pulsed conversion operations.
<code>AI_VRead</code>	Reads an analog input channel (initiates an A/D conversion on an analog input channel) and returns the result scaled to a voltage in units of volts.
<code>AI_VScale</code>	Converts the binary result from an <code>AI_Read</code> call to the actual input voltage.

Single-Channel Analog Input Application Tips

All of the Traditional NI-DAQ functions described in this section are for nonbuffered single-point analog input readings. For buffered data acquisition, refer to the [Data Acquisition Functions](#) section.

Two of the AI functions are related to device configuration. If you have changed the device jumper settings from the factory-default settings or want to reprogram the E Series devices, call `AI_Configure` at the beginning of your application to inform Traditional NI-DAQ about the changes. Furthermore, if you have connected multiplexer devices (AMUX-64T) to your MIO and AI devices, call `AI_Mux_Config` once at the beginning of your application to inform Traditional NI-DAQ about the multiplexer devices.

For most purposes, `AI_VRead` is the only function required to perform single-point analog input readings. Use `AI_Read` when unscaled data is sufficient or when extra time taken by `AI_VRead` to scale the data is detrimental to your applications. Use `AI_VScale` to convert the binary

values to voltages at a later time if you want. Refer to Figure 3-1 for the function flow typical of single-point data acquisition. Also, refer to the *NI-DAQ Examples Online Help* (`niDAQex.hlp`) to find a related example.

When using SCXI as a front end for analog input to the MIO and AI devices, it is not advisable to use the `AI_VRead` function because that function does not take into account the gain of the SCXI module when scaling the data. Use the `AI_Read` function to obtain the unscaled data, then call the `SCXI_Scale` function using both the SCXI module gain and the DAQ device gain.

Figure 3-1. Single-Point Analog Reading with Onboard Conversion Timing

When accurate sample timing is important, you can use external conversion pulses with `AI_Clear`, `AI_Setup`, and `AI_Check` to sample your signal on the analog input channels. Refer to Figure 3-2 for the function flow typical of single-point data acquisition using external conversion pulses. However, this method works only if your computer is faster than the rate of conversion pulses. Refer to the [Data Acquisition Functions](#) section to learn more about interrupt and DMA-driven data acquisition by using high-speed data acquisition.

When you are using SCXI analog input modules, use the SCXI functions to set up the SCXI chassis and modules *before* using the AI functions described in Figures 3-1 and 3-2.

Figure 3-2. Single-Point Analog Reading with External Conversion Timing

Data Acquisition Functions

High-Level Data Acquisition Functions

These high-level data acquisition functions are synchronous calls that acquire data and return when data acquisition is complete.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

DAQ_Op

Performs a synchronous, single-channel data acquisition operation. **DAQ_Op** does

not return until Traditional NI-DAQ has acquired all the data or an acquisition error has occurred.

DAQ_to_Disk

Performs a synchronous, single-channel data acquisition operation and saves the acquired data in a disk file.

DAQ_to_Disk does not return until Traditional NI-DAQ has acquired and saved all the data or an acquisition error has occurred.

Lab_ISCAN_Op

Performs a synchronous, multiple-channel scanned data acquisition operation. Lab_ISCAN_Op does not return until Traditional NI-DAQ has acquired all the data or an acquisition error has occurred.

Lab_ISCAN_to_Disk

Performs a synchronous, multiple-channel scanned data acquisition operation and simultaneously saves the acquired data in a disk file.

Lab_ISCAN_to_Disk does not return until Traditional NI-DAQ has acquired all the data and saved all the data or an acquisition error has occurred.

SCAN_Op

Performs a synchronous, multiple-channel scanned data acquisition operation. SCAN_Op does not return until Traditional NI-DAQ has acquired all the data or an acquisition error has occurred.

SCAN_to_Disk

Performs a synchronous, multiple-channel scanned data acquisition operation and simultaneously saves the acquired data in a disk file.

SCAN_to_Disk does not return until Traditional NI-DAQ has acquired all the data and saved it or until an acquisition error has occurred.

Low-Level Data Acquisition Functions

These functions are low-level primitives used for setting up, starting, and monitoring asynchronous data acquisition operations.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

<code>DAQ_Check</code>	Checks if the current data acquisition operation is complete and returns the status and the number of samples acquired to that point.
<code>DAQ_Clear</code>	Cancels the current data acquisition operation (both single-channel and multiple-channel scanned) and reinitializes the data acquisition circuitry.
<code>DAQ_Config</code>	Stores configuration information for subsequent data acquisition operations.
<code>DAQ_Monitor</code>	Returns data from an asynchronous data acquisition in progress. During a multiple-channel acquisition, you can call <code>DAQ_Monitor</code> to retrieve data from a single channel or from all channels being scanned. Using the oldest/newest mode, you can specify whether <code>DAQ_Monitor</code> returns sequential (oldest) blocks of data, or the most recently acquired (newest) blocks of data.
<code>DAQ_Rate</code>	Converts a data acquisition rate into the timebase and sample-interval values needed to produce the rate you want.
<code>DAQ_Set_Clock</code>	Sets the scan rate for a group of channels.
<code>DAQ_Start</code>	Initiates an asynchronous, single-channel data acquisition operation and stores its input in an array.
<code>DAQ_StopTrigger_Config</code>	Enables the pretrigger mode of data acquisition and indicates the number of data points to acquire after you apply the

	stop trigger pulse at the appropriate PFI pin.
<code>DAQ_VScale</code>	Converts the values of an array of acquired binary data and the gain setting for that data to actual input voltages measured.
<code>Lab_ISCAN_Check</code>	Checks if the current scan data acquisition operation begun by the <code>Lab_ISCAN_Start</code> function is complete and returns the status, the number of samples acquired to that point, and the scanning order of the channels in the data array.
<code>Lab_ISCAN_Start</code>	Initiates a multiple-channel scanned data acquisition operation and stores its input in an array.
<code>SCAN_Demux</code>	Rearranges, or demultiplexes, data acquired by a <code>SCAN</code> operation into row-major order (that is, each row of the array holding the data corresponds to a scanned channel) for easier access by C applications. <code>SCAN_Demux</code> does not need to be called by BASIC applications to rearrange two-dimensional arrays because these arrays are accessed in column-major order.
<code>SCAN_Sequence_Demux</code>	Rearranges the data produced by a multirate acquisition so that all the data from each channel is stored in adjacent elements of your buffer.
<code>SCAN_Sequence_Retrieve</code>	Returns the scan sequence created by Traditional NI-DAQ as a result of a previous call to <code>SCAN_Sequence_Setup</code> .
<code>SCAN_Sequence_Setup</code>	Initializes the device for a multirate scanned data acquisition operation. Initialization includes selecting the channels to be scanned, assigning gains to

these channels, and assigning different sampling rates to each channel by dividing down the base scan rate.

`SCAN_Setup`

Initializes circuitry for a scanned data acquisition operation. Initialization includes storing a table of the channel sequence and gain setting for each channel to be digitized.

`SCAN_Start`

Initiates a multiple-channel scanned data acquisition operation, with or without interval scanning, and stores its input in an array.

Low-Level Double-Buffered Data Acquisition Functions

These functions are low-level primitives used for setting up and monitoring asynchronous double-buffered data acquisition operations.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

`DAQ_DB_Config`

Enables or disables double-buffered data acquisition operations.

`DAQ_DB_HalfReady`

Checks if the next half buffer of data is available during a double-buffered data acquisition.

`DAQ_DB_Transfer`

Transfers half of the data from the buffer being used for double-buffered data acquisition to another buffer, which is passed to the function. This function waits until the data to be transferred is available before returning. You can execute `DAQ_DB_Transfer` repeatedly to return sequential half buffers of the data.

Data Acquisition Application Tips

LPM Device Counter/Timer Signals

For these devices, counter 0 produces the sample interval for data acquisition timing. If data acquisition is not in progress, you can call the `ICTR` functions to use counter 0 as a general-purpose counter. Because the `CLOCK0` input is connected to a 1 MHz oscillator, the timebase for counter 0 is fixed.

External Multiplexer Support (AMUX-64T)

You can expand the number of analog input signals measurable by the MIO and AI devices with an external multiplexer device (AMUX-64T). Refer to the *AMUX-64T User Manual* for more information on the external multiplexer device.

Basic Building Blocks

Most of the buffered data acquisition applications are made up of four building blocks, as shown in Figure 3-3. However, depending on the specific devices and applications you have, the Traditional NI-DAQ functions comprising each building block vary. Typical applications can include the Traditional NI-DAQ functions in each of their four building blocks.

Figure 3-3. Buffered Data Acquisition Basic Building Blocks

When using SCXI analog input modules, use the SCXI functions to set up the SCXI chassis and modules before using the `AI`, `DAQ`, `SCAN`, and `Lab_ISCAN` functions shown in the following flowcharts.

Building Block 1: Configuration

Five configuration functions are available for creating the first building block, as shown in Figure 3-4. However, you do not have to call all five functions every time you start a data acquisition.

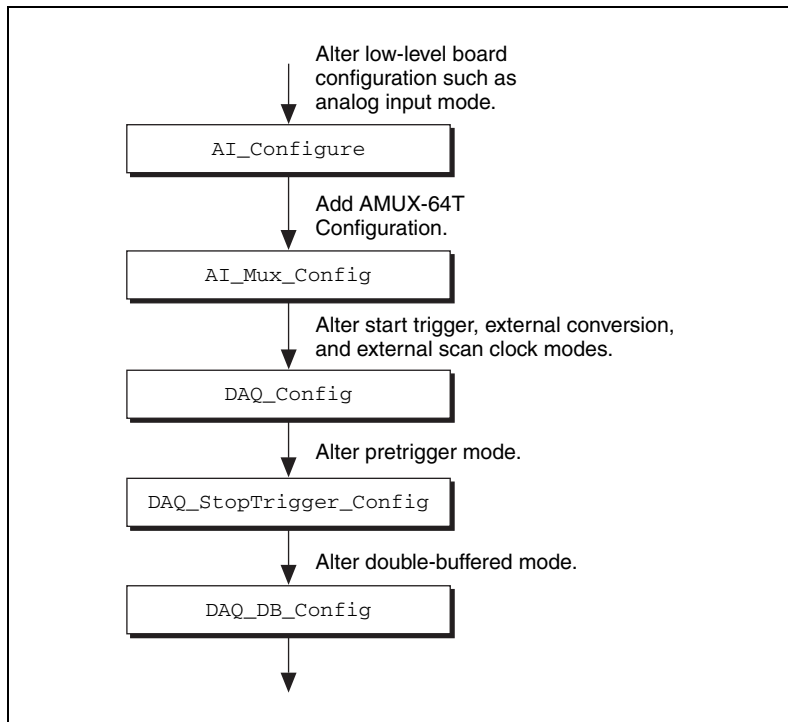

Figure 3-4. Buffered Data Acquisition Application Building Block 1, Configuration

Traditional NI-DAQ records the device configurations and the default configurations. Refer to the `Init_DA_Brds` description in the *Traditional NI-DAQ C Reference Help* for device default configurations. Therefore, if you are satisfied with the default or the current configurations of your devices, your configuration building block will be empty, and you can go on to the next building block, Start.

Building Block 2: Start

Traditional NI-DAQ has high-level and low-level start functions. The high-level start functions are as follows:

- `DAQ_Op`
- `SCAN_Op` (MIO, AI, and DSA devices only)

- Lab_ISCAN_Op (LPM devices only)
- DAQ_to_Disk
- SCAN_to_Disk (MIO, AI, and DSA devices only)
- Lab_ISCAN_to_Disk (LPM devices only)

A high-level start call initiates data acquisition but does not return to the function caller until the data acquisition is complete. For that reason, you do not need the next building block, Checking, when you use high-level start functions.

Figure 3-5. Buffered Data Acquisition Application Building Block 2, Start

The major advantage of the high-level start functions is that they are simple. A single call can produce a buffer full or a disk full of data. However, if your application is acquiring data at a very slow rate or is acquiring a lot of data, the high-level start functions might tie up the computer for a significant amount of time. Therefore, Traditional NI-DAQ has some low-level (or asynchronous) start functions that initiate data acquisition and return to the calling program function caller immediately.

Asynchronous start functions include DAQ_Start, SCAN_Start, and Lab_ISCAN_Start. Figures 3-6 and 3-7 show how the start calls make up building block 2 for different devices.

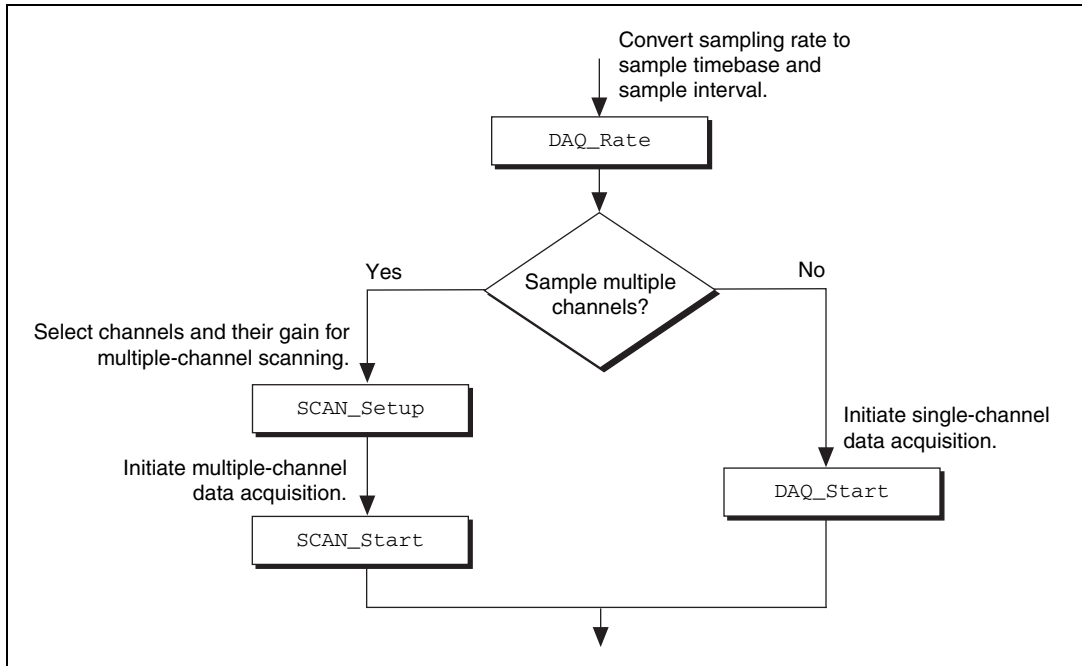

Figure 3-6. Buffered Data Acquisition Application Building Block 2, Start, for the MIO, AI, and DSA Devices

For DSA devices, substitute DAQ_Set_Clock for DAQ_Rate in Figure 3-6. DAQ_Rate will not produce the correct clock settings for DSA devices.

If your device works with *multirate scanning*, you can use SCAN_Sequence_Setup instead of SCAN_Setup in building block 2.

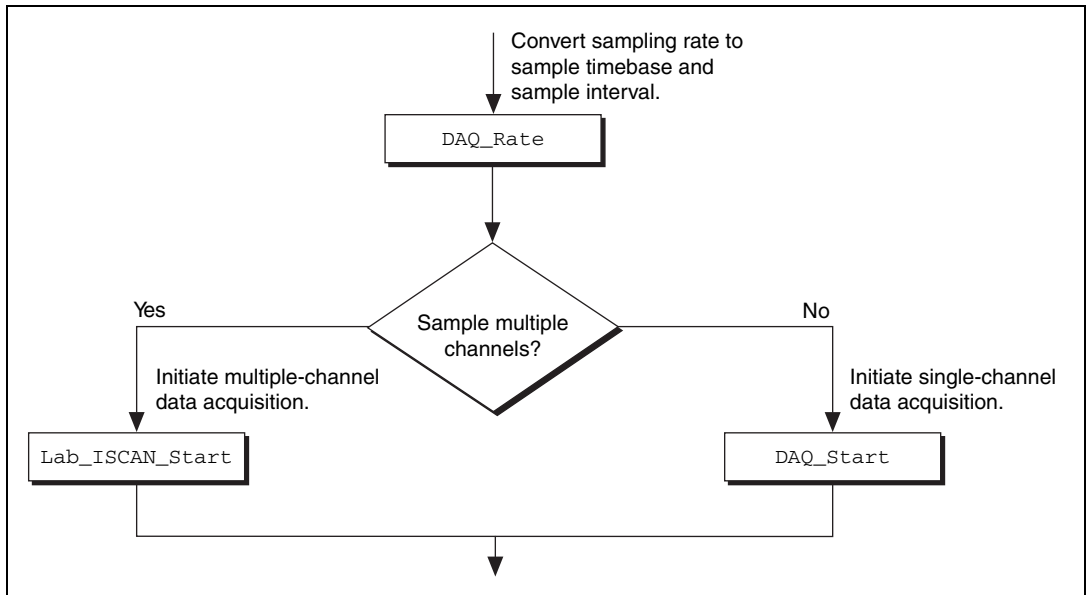

Figure 3-7. Buffered Data Acquisition Application Building Block 2, Start, for the LPM Devices

When you have the asynchronous start calls in your building block 2, the next building block, Checking, is very useful for determining the status of the ongoing data acquisition process.

Building Block 3: Checking

DAQ_Check and Lab_ISCAN_Check, shown in Figures 3-8 and 3-9, are simple and quick ways to check the ongoing data acquisition process. This call is often put in a while loop so that the application can periodically monitor the data acquisition process.

Figure 3-8. Buffered Data Acquisition Application Building Block 3, Checking, for the MIO, AI, and DSA Devices

Figure 3-9. Buffered Data Acquisition Application Building Block 3, Checking, for the LPM Devices

However, if the information provided by DAQ_Check is not sufficient, DAQ_Monitor or the double-buffered functions might be a better choice. With DAQ_Monitor, not only can you monitor the data acquisition

process, but you can also retrieve a portion of the acquired data. With the double-buffered functions, you can retrieve half of the data buffer at a time. Double-buffered functions are very useful when your application has a real-time strip chart displaying the incoming data.

Building Block 4: Cleaning up

The purpose of this building block is to stop the data acquisition and free any system resources (such as DMA channels) used for the data acquisition. `DAQ_Clear` is the only function needed for this building block and is automatically called by the check functions described in the previous building block when the data acquisition is complete. Therefore, you can eliminate this last building block if your application continuously calls the previously described check functions until the data acquisition is complete.

Note `DAQ_Clear` does not alter the device configurations made by building block 1.

Double-Buffered Data Acquisition

The double-buffered (`DAQ_DB`) data acquisition functions return data from an ongoing data acquisition without interrupting the acquisition. These functions use a double or circular buffering scheme that permits half buffers of data to be retrieved and processed as the data becomes available. By using a circular buffer, you can collect an unlimited amount of data without needing an unlimited amount of memory. Double-buffered data acquisition is useful for applications such as streaming data to disk and real-time data display.

Initiating double-buffered data acquisition requires some simple changes to the first and third basic building blocks, Configuration and Checking, respectively.

In building block 1, turn on double-buffered mode data acquisition through the `DAQ_DB_Config` call. After the double-buffered mode is enabled, all subsequent data acquisitions are in double-buffered mode.

In building block 3, different checking functions are needed. Figure 3-10 shows a simple way to monitor the data acquisition in progress and to retrieve data when they are available.

For further details on double-buffered data acquisition, refer to Chapter 4, *Traditional NI-DAQ Double Buffering*.

Figure 3-10. Double-Buffered Data Acquisition Application
Building Block 3, Checking

Multirate Scanning

Use multirate scanning to scan multiple channels at different scan rates and acquire the minimum amount of data necessary for your application. This is particularly useful if you are scanning very fast and want to write your data to disk, or if you are acquiring large amounts of data and want to keep your buffer size to a minimum.

Multirate scanning works by scanning each channel at a rate that is a fraction of the specified scan rate. For example, if you want to scan four channels at 6,000, 4,000, 3,000, and 1,000 scans per second, specify a scan rate of 12,000 scans per second and a scan rate divisor vector of 2, 3, 4, and 12.

NI-DAQ includes three functions for multirate scanning:

- `SCAN_Sequence_Setup`
- `SCAN_Sequence_Retrieve`
- `SCAN_Sequence_Demux`

Use `SCAN_Sequence_Setup` to identify the channels to scan, their gains, and their scan rate divisors. After the data is acquired, use `SCAN_Sequence_Retrieve` and `SCAN_Sequence_Demux` to arrange the data into a more convenient format.

Figure 3-11 shows how to use the multirate scanning functions in conjunction with other Traditional NI-DAQ functions.

Figure 3-11. Multirate Scanning

Analog Output Function Group

The Analog Output function group contains two sets of functions—the Analog Output (AO) functions, which perform single *D/A* conversions, and the Waveform (WFM) functions, which perform buffered D/A conversions.

Note Use the SCXI functions described later in this chapter for the SCXI-1124 analog output module.

One-Shot Analog Output Functions

Use the Analog Output functions to perform single D/A conversions with analog output devices.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

<code>AO_Change_Parameter</code>	Selects a specific parameter setting for the analog output section or analog output channel. These parameters might be data transfer conditions, filter settings, or similar device settings.
<code>AO_Configure</code>	Records the output range and polarity selected for each analog output channel by the jumper settings on the device and indicates the update mode of the DACs. Use this function if you have changed the jumper settings affecting analog output range and polarity from their factory settings. Also use this function to change the analog output settings on devices without jumpers.
<code>AO_Update</code>	Updates analog output channels on the specified device to new voltage values when the later internal update mode is enabled by a previous call to <code>AO_Configure</code> .
<code>AO_VScale</code>	Scales a voltage to a binary value that, when written to one of the analog output channels, produces the specified voltage.

`AO_VWrite`

Accepts a floating-point voltage value, scales it to the proper binary number, and writes that number to an analog output channel to change the output voltage.

`AO_Write`

Writes a binary value to one of the analog output channels, changing the voltage produced at the channel.

Analog Output Application Tips

This section contains a basic explanation of how to construct an application using the analog output functions. The flowcharts are a quick reference for constructing potential applications from the Traditional NI-DAQ function calls.

For most purposes, `AO_VWrite` is the only function required to generate single analog voltages. It converts the floating-point voltage to binary and writes the value to the device. `AO_VWrite` is the equivalent of a call to `AO_VScale` followed by a call to `AO_Write`. Figure 3-12 illustrates the equivalency.

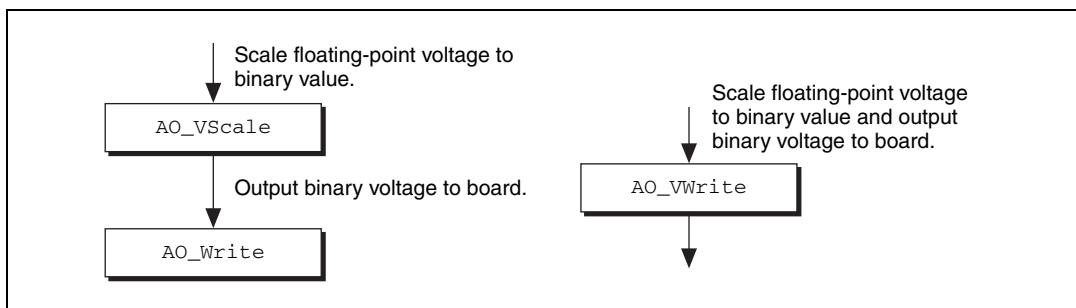

Figure 3-12. Equivalent Analog Output Calls

The following applications are shown using `AO_VWrite`. However, substituting the equivalent `AO_VScale` and `AO_Write` calls will not change the results.

Simple Analog Output Application

Figure 3-13 illustrates the basic series of calls for a simple analog output application.

Figure 3-13. Simple Analog Output Application

The call to `AO_Configure` in Figure 3-13 must be made only if you have changed the jumper settings of an MIO or AT-AO-6/10 device. You also might call `AO_Configure` to enable external updating of the voltage. When you select external update mode, voltages written to the device are not output until you apply a pulse to pin 48 (EXTUPDATE*) on the AT-AO-6/10 or to the selected pin on an E Series, 671X, or 673X device. You can simultaneously change the voltages at all the analog output channels. The final steps in Figure 3-13 form a simple loop. New voltages are output until the data ends.

Analog Output with Software Update Application

Another application option is to enable later software updates. Like the external update mode, voltages written to the device are not immediately output. Instead, the device does not output the voltages until you call `AO_Update`. In later software update mode, the device changes voltages simultaneously at all the channels. Figure 3-14 illustrates a modified version of the flowchart in Figure 3-13.

Figure 3-14. Analog Output with Software Updates

The first modification you make is to enable later internal updates when you call `AO_Configure`. The next change, which follows the `AO_VWrite` step, is the decision to wait or to output the voltage. If you want the voltage to be output, your application must call `AO_Update` to write out the voltage. The rest of the flowchart is identical to Figure 3-13.

Note Implement buffered analog output using the Waveform Generation (WFM) functions.

Waveform Generation Functions

Use the Waveform Generation (WFM) functions to perform buffered analog output operations with the MIO devices, 671X devices, 673X devices, and AT-AO-6/10 devices.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

High-Level Waveform Generation Functions

The following high-level Waveform Generation functions accomplish with a single call tasks that require several low-level calls to accomplish:

<code>WFM_from_Disk</code>	Assigns a disk file to one or more analog output channels, selects the rate and the number of times the data in the file is to be generated, and starts the generation. <code>WFM_from_Disk</code> always waits for completion before returning, unless you call <code>Timeout_Config</code> .
<code>WFM_Op</code>	Assigns a waveform buffer to one or more analog output channels, selects the rate and the number of times the data in the buffer is to be generated, and starts the generation. If the number of buffer generations is finite, <code>WFM_Op</code> waits for completion before returning, unless you call <code>Timeout_Config</code> .

Low-Level Waveform Generation Functions

Low-level Waveform Generation functions are for setting up, starting, and controlling synchronous waveform generation operations:

<code>WFM_Chan_Control</code>	Temporarily halts or restarts waveform generation for a single analog output channel.
<code>WFM_Check</code>	Returns status information concerning a waveform generation operation.
<code>WFM_ClockRate</code>	Sets an update rate and a delay rate for a group of analog output channels.

WFM_DB_Config	Enables and disables the double-buffered mode of waveform generation.
WFM_DB_HalfReady	Checks if the next half buffer for one or more channels is available for new data during a double-buffered waveform generation operation. You can use <code>WFM_DB_HalfReady</code> to avoid the waiting period possible with the double-buffered transfer functions.
WFM_DB_Transfer	Transfers new data into one or more waveform buffers (selected in <code>WFM_Load</code>) as waveform generation is in progress. <code>WFM_DB_Transfer</code> waits until Traditional NI-DAQ can transfer the data from the buffer to the waveform buffer.
WFM_Group_Control	Controls waveform generation for a group of analog output channels.
WFM_Group_Setup	Assigns one or more analog output channels to a waveform generation group. By default, all analog output channels for 671X, 673X, and MIO devices are in group 1.
WFM_Load	Assigns a waveform buffer to one or more analog output channels and indicates the number of waveform cycles to generate. For the 671X devices, 673X devices, and E Series devices, this function also enables or disables FIFO mode waveform generation.
WFM_Rate	Converts a waveform generation update rate into the timebase and update-interval values needed to produce the rate you want.
WFM_Scale	Translates an array of floating-point values that represent voltages into an array of binary values that produce those voltages. The function uses the current

analog output configuration settings to perform the conversions.

`WFM_Set_Clock` Sets an update rate for a group of channels.

Waveform Generation Application Tips

This section outlines a basic explanation of constructing an application with the Waveform Generation functions. The flowcharts are a quick reference for constructing potential applications from the Traditional NI-DAQ function calls.

Basic Waveform Generation Applications

A basic waveform application outputs a series of voltages to an analog output channel. Figure 3-15 illustrates the ordinary series of calls for a basic waveform application.

The first step of Figure 3-15 calls `WFM_Scale`. The `WFM_Scale` function converts floating-point voltages to integer values, thus producing the voltages (DAC values) you want.

You have two options available for starting a waveform generation. The first option is to call the high-level function `WFM_Op`. The `WFM_Op` function immediately begins the waveform generation after you call it. If the number of *iterations* is nonzero, `WFM_Op` does not return until the waveform generation is done and all cleanup work is complete. Setting the iterations equal to 0 signals Traditional NI-DAQ to place the waveform generation in continuous double-buffered mode. In continuous double-buffered mode, waveform generation occurs in the background, and the `WFM_Op` function returns immediately to your application. Refer to the *Double-Buffered Waveform Generation Applications* section for more information.

The second option to start a waveform generation is to call the following sequence of functions:

1. `WFM_Group_Setup` to assign one or more analog output channels to a group.
2. `WFM_Load` to assign a waveform buffer to one or more analog output channels.
3. `WFM_Rate` to convert a data output rate to a timebase and an update interval that generates the rate you want. `WFM_Rate` only supports some devices. Because it does not have a **device number** parameter,

it cannot return an error if you use it with a non-supported device. Refer to the *Traditional NI-DAQ C Reference Help* for supported devices.

4. `WFM_ClockRate` or `WFM_Set_Clock` to set the update rate. Refer to the *Traditional NI-DAQ C Reference Help* to find out which function supports your device.
5. `WFM_Group_Control` (with **operation** = `START`) to start the waveform generation in the background and return to your application after the waveform generation has begun.

The next step in Figure 3-15 shows how the call to `WFM_Check`. `WFM_Check` retrieves the current status of the waveform generation. Your application uses this information to determine if the generation is complete or should be stopped.

The final step is to call `WFM_Group_Control` (**operation** = `CLEAR`). The `CLEAR` operation performs all of the necessary cleanup work after a waveform generation. Additionally, `CLEAR` halts any ongoing waveform generation.

Figure 3-15. Basic Waveform Generation Application

Basic Waveform Generation with Pauses

The application skeleton described in this section is nearly identical to the basic waveform generation application skeleton. The difference is that the description in this section includes the pause and resume operations. Figure 3-16 illustrates the ordinary series of calls for a basic waveform application with pauses.

The first step of Figure 3-16 calls `WFM_Group_Setup`. The `WFM_Group_Setup` function assigns one or more analog output channels to a group.

The second step is to assign a buffer to the analog output channels using the calls `WFM_Scale` and `WFM_Load`. The `WFM_Scale` function converts floating-point voltages to integer values that produce the voltages you want. The `WFM_Load` function assigns a waveform buffer to one or more analog output channels.

The next step is to assign an update rate to the group of channels using the calls `WFM_Rate` and `WFM_ClockRate`. The `WFM_Rate` function converts a data output rate to a timebase and an update interval that generates the rate you want. The `WFM_ClockRate` function assigns a timebase, update interval, and delay interval to a group of analog output channels.

Notice that there are restrictions for using the `WFM_ClockRate` function to specify delay rate. Refer to the `WFM_ClockRate` function description in the *Traditional NI-DAQ C Reference Help* for further details.

Your application is now ready to start a waveform generation. Call `WFM_Group_Control` (**operation** = `START`) to start the waveform generation in the background. `WFM_Group_Control` will return to your application after the waveform generation begins.

The next step in Figure 3-16 is an application decision to pause the waveform generation. The application uses a number of conditions for making this decision, including status information returned by `WFM_Check`.

Pause the waveform generation by calling `WFM_Group_Control` (**operation** = `PAUSE`). `PAUSE` stops the waveform generation and maintains the current waveform voltage at the channel output.

Resume the waveform generation by calling `WFM_Group_Control` (**operation** = `RESUME`). `RESUME` restarts the waveform generation at the data point where it was paused. The output rate and the data buffer are unchanged.

The final step is to call `WFM_Group_Control` (**operation** = `CLEAR`). `CLEAR` performs all the necessary cleanup work after a waveform generation. Additionally, `CLEAR` halts any ongoing waveform generation.

Figure 3-16. Waveform Generation with Pauses

Double-Buffered Waveform Generation Applications

You also can configure waveform generation as a double-buffered operation. Double-buffered operations can perform continuous waveform generation with a limited amount of memory. For an explanation of double buffering, refer to Chapter 4, *Traditional NI-DAQ Double Buffering*. Figure 3-17 outlines the basic steps for double-buffered waveform applications.

First, enable double buffering by calling `WFM_DB_Config` as shown in the first step of Figure 3-17.

Although every step is not in the diagram, you might also call `WFM_Rate` and/or `WFM_Scale` as described in the basic waveform application outline.

There are two ways in which your application can start waveform generation. The first way is to call the high-level function `WFM_Op`. The second way is to call the following sequence of functions—`WFM_Group_Setup` (only required on the AT-AO-6/10), `WFM_Load`, `WFM_ClockRate`, or `WFM_Set_Clock`, `WFM_Group_Control` (**operation** = `START`). The `WFM_Group_Setup` function assigns one or more analog output channels to a group. The `WFM_Load` function assigns a waveform buffer to one or more analog output channels. This buffer is called a *circular buffer*. The `WFM_ClockRate` and `WFM_Set_Clock` functions assign an update rate to a group of analog output channels. Refer to the *Traditional NI-DAQ C Reference Help* for the function that supports your device. Calling `WFM_Group_Control` (**operation** = `START`) starts the background waveform generation. `WFM_Group_Control` returns to your application after the waveform generation begins.

After the operation begins, you can perform unlimited transfers to the circular waveform buffer. To transfer data to the circular buffer, call the `WFM_DB_Transfer` function. After you call the function, Traditional NI-DAQ waits until it is able to transfer the data before returning to the application. To avoid the waiting period, you can call `WFM_DB_HalfReady` to determine if the transfer can be made immediately. If `WFM_DB_HalfReady` indicates Traditional NI-DAQ is not ready for a transfer, your application is free to do other processing and check the status later.

After the final transfer, you can call `WFM_Check` to get the current transfer progress. Remember, Traditional NI-DAQ requires some time after the final transfer to actually output the data.

The final step is to call `WFM_Group_Control` (**operation** = `CLEAR`). The `CLEAR` operation performs all of the necessary cleanup work after a waveform generation. Additionally, `CLEAR` halts any ongoing waveform generation.

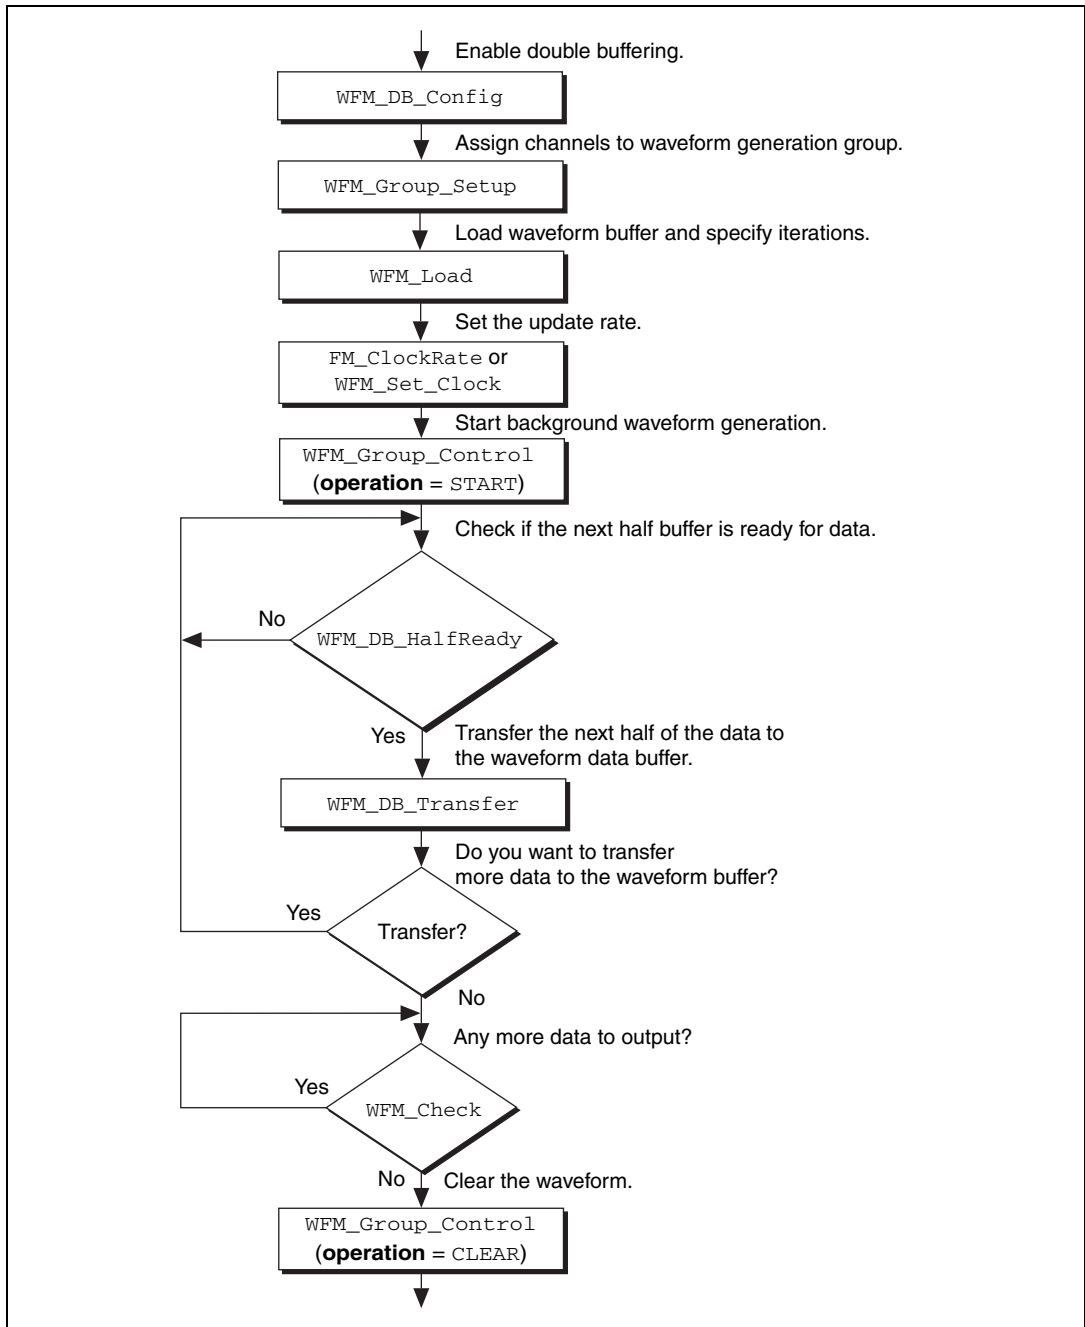

Figure 3-17. Double-Buffered Waveform Generation

Reference Voltages for Analog Output Devices

Table 3-4 shows the output voltages produced when you select unipolar output polarity.

Table 3-4. Output Voltages with Unipolar Output Polarity

Device	Value in Waveform Buffer		
	0	4,095	65,535
AT-MIO-16XE-10, PCI-MIO-16XE-10, PCI-MIO-16XE-50, PCI-6031E (MIO-64XE-10), 6052E devices	0 V	—	Reference voltage
All other MIO devices	0 V	Reference voltage	—

Table 3-5 shows the output voltages produced when you select bipolar output polarity.

Table 3-5. Output Voltages with Bipolar Output Polarity

Device	Value in Waveform Buffer			
	–2,048	2,047	–32,768	32,767
AT-MIO-16XE-10, PCI-MIO-16XE-10, PCI-MIO-16XE-50, PCI-6031E (MIO-64XE-10), PCI-6110, PCI-6111, 6052E devices	—	—	Negative of the reference voltage	Reference voltage
All other MIO devices, 671X devices	Negative of the reference voltage	Reference voltage	—	—
AT-AO-6/10	Negative of the reference voltage (–10 V in default case)	Reference voltage (+10 V in default case)	—	—
673X devices	—	—	Negative of the reference voltage	Reference voltage

Note NI PCI-4451 and NI PCI-4551 devices use signed, 18-bit binary data left-justified in a 32-bit word. Their output voltage range is ± 10 V.

Minimum Update Intervals

The rate at which a device can output analog data is limited by the performance of the host computer. For waveform generation, the limitation is in terms of minimum update intervals. The update interval is the period of time between outputting new voltages. Therefore, the minimum update interval specifies the smallest possible time delay between outputting new data points. In other words, the minimum update interval specifies the fastest rate at which a device can output data. Refer to Chapter 4, [Traditional NI-DAQ Double Buffering](#), for more information on the minimum update intervals.

Counter Usage

NI PCI-4451 and NI PCI-4551 devices use the same counter for both waveform generation and analog input data acquisition. Refer to the `WFM_Set_Clock` function in the *Traditional NI-DAQ C Reference Help* for an explanation of the restrictions this causes. This counter is separate from the general-purpose counters.

The MIO, 671X, 673X, and E Series devices use dedicated counters from the DAQ-STC chip for waveform-generation control and timing.

On the AT-AO-6/10, counter 0 produces the total update interval for group 1 waveform generation, and counter 1 produces the total update interval for group 2 waveform generation. However, if the total update interval is greater than 65,535 μ s for either group 1 or 2, counter 2 is used by counter 0 (group 1) or counter 1 (group 2) to produce the total update interval. If either group is using counter 2 to produce the sample timebase, counter 2 is available to the other group only if the timebase is the same as the timebase required by the Waveform Generation functions to produce the total update interval. In this case, counter 2 produces the same timebase for both waveform generation groups.

FIFO Lag Effect on the MIO, E Series, NI 4451 for PCI, NI 4551 for PCI, 671X, and 673X Devices

Group 1 analog output channels use an onboard FIFO to output data values to the DACs. Traditional NI-DAQ continuously writes values to the FIFO as long as the FIFO is not full. Traditional NI-DAQ transfers data values from the FIFO to the DACs at regular intervals using an onboard or external clock. You see a lag effect for group 1 channels because of the FIFO

buffering. That is, a value written to the FIFO is not output to the DAC until all of the data values currently in the FIFO have been output to the DACs. This time lag is dependent upon the update rate (specified in `WFM_ClockRate`). Refer to your device user manual for a more detailed discussion of the onboard FIFO.

Three functions are affected by the FIFO lag effect—`WFM_Chan_Control`, `WFM_Check`, and double-buffered waveform generation.

- `WFM_Chan_Control`—When you execute **operation** = PAUSE for a group 1 channel, the effective pause does not occur until the FIFO has finished writing all of the data remaining in the FIFO for the specified channel. The same is true for the RESUME operation on a group 1 channel; Traditional NI-DAQ cannot place data for the specified channel into the FIFO until the FIFO is empty.
- `WFM_Check`—The values returned in **pointsDone** and **itersDone** indicate the number of points that Traditional NI-DAQ has written to the FIFO for the specified channel. A time lag occurs from the point when Traditional NI-DAQ writes the data to the FIFO when Traditional NI-DAQ outputs the data to the DAC.
- When you use double-buffered waveform generation with group 1, make sure the total number of points for all of the group 1 channels (specified in the **count** parameter in `WFM_Load`) is at least twice the size of the FIFO. Refer to your device user manual for information on the analog output FIFO size.
- For 61XX devices with onboard memory, data is transferred to the memory in blocks of 32 bytes. Therefore, when you use double-buffered waveform generation that does not end in a 32-byte sample boundary, the last few points will not be output.

With PCI E Series, 671X devices, and 673X devices in NI-DAQ 5.1 and later, you can reduce or even eliminate the FIFO lag effect by specifying the FIFO condition Traditional NI-DAQ uses to determine when to put more data into the FIFO. Refer to the `AO_Change_Parameter` function in *Traditional NI-DAQ C Reference Help* for details.

Externally Triggering Your Waveform Generation Operation

You can initiate a waveform generation operation from an external trigger signal in much the same manner as for analog input. Refer to the `Select_Signal` function in the *Traditional NI-DAQ C Reference Help*.

Digital I/O Function Group

The Digital I/O function group contains three sets of functions—the Digital I/O (DIG) functions, the Group Digital I/O (DIG_Block, DIG_Grp, and DIG_SCAN) functions, and the double-buffered Digital I/O (DIG_DB) functions. Refer to the *NI-DAQ Functions Listed by Hardware Product* section of the *Traditional NI-DAQ C Reference Help* to find out which digital functions your device supports. The SCXI functions control the SCXI digital and relay modules.

These devices contain a number of digital I/O ports of up to eight digital lines in width. The name *port* refers to a set of digital lines. Digital lines are also referred to as bits in this text. In many instances, you control the set of digital lines as a group for both reading and writing purposes and for configuration purposes. For example, you can configure the port as an input port or as an output port, which means that the set of digital lines making up the port consist of either all input lines or all output lines.

In NI-DAQ, you refer to ports by number. Many digital I/O devices label ports by letter. For these devices, use port number 0 for port A, port number 1 for port B, and so on. For example, the DIO-24 contains three ports of eight digital lines each. Ports 0, 1, and 2 are labeled PA, PB, and PC on the DIO-24 I/O connector. The eight digital lines making up port 0, lines 0 through 7, are labeled PA0 through PA7.

In some cases, you can combine digital I/O ports into a larger entity called a *group*. On the 653X devices, for example, you can assign any of the ports DIOA through DIOD to one of two groups. On the PCI-6115, PCI-6120, and 673X devices, you also can create groups smaller than the port size. For example, both the PCI-6115 and the PCI-6120 have one digital port of eight lines, but you can configure five lines as an input group and three lines as an output group. A group of ports are handshaked or clocked as a unit.

The digital I/O functions can write to and read from both an entire port and single digital lines within the port. To write to an entire port, Traditional NI-DAQ writes a *byte* of data to the port in a specified digital output pattern. To read from a port, Traditional NI-DAQ returns a byte of data in a specified digital output pattern. The byte mapping to the digital I/O lines is as follows.

Table 3-6. Byte Mapping to Digital I/O Lines

Bit Number	Digital I/O Line Number
7	7 Most significant bit (<i>MSB</i>)
6	6
5	5
4	4
3	3
2	2
1	1
0	0 Least significant bit (LSB)

In the cases where a digital I/O port has fewer than eight lines, the most significant bits in the byte format are ignored.

You can configure most of the digital I/O ports as either input ports or output ports. On the 653X, DSA, 671X, 673X, and E Series devices (except for ports 2, 3, and 4 on the AT-MIO-16DE-10), you can program lines on the same port independently as input or output lines. Some digital I/O ports are permanently fixed as either input ports or output ports. If you configure a port as an input port, reading that port returns the value of the digital lines. In this case, external devices connected to and driving those lines determine the state of the digital lines.

If no external device is driving the lines, the lines float to some indeterminate state, and you can read them in either state 0 (digital logic low) or state 1 (digital logic high). If you configure a port as an output port, writing to the port sets each digital line in the port to a digital logic high or low, depending on the data written. In this case, these digital lines can drive an external device. Many of the digital I/O ports have read-back capability; if you configure the port as an output port, reading the port returns the output state of that port.

You can use digital I/O ports on the DIO-24, 6025E devices, DIO-96, 653X, DIO-32F, 673X, PCI-6115, and PCI-6120 devices for handshaking and no-handshaking modes. These two modes have the following characteristics:

- No-handshaking mode—This mode changes the digital value at an output port when written to and returns a digital value from a digital input port when read from. No handshaking signals are generated.
- Handshaking mode—This mode is for digital I/O handshaking; that is, a digital input port latches the data present at the input when the port receives a handshake signal and generates a handshake pulse when the computer writes to a digital output port. In this mode, you can read the status of a port or a group of ports to determine whether an external device has accepted data written to an output port or has latched data into an input port. The handshaking mode for the PCI 6115, PCI-6120, and 673X devices is slightly different and is more appropriately called a clocking mode. In the clocking mode, no two-way handshaking signals are generated. Instead, data is latched in or latched out when a pulse from a clock signal is detected.

Note On the 653X, PCI-6115, PCI-6120, and 673X devices, you must assign ports to a group before you can use handshaking mode.

Process control applications, such as controlling or monitoring relays, often use the no-handshaking mode. Communications applications, such as transferring data between two computers, often use the handshaking mode.

DIO-24, 6025E, AT-MIO-16DE-10, and DIO-96 Device Groups

You can group together any combination of ports 0, 1, 3, 4, 6, 7, 9, and 10 on the DIO-96, ports 0 and 1 on the DIO-24, and ports 2 and 3 on the 6025E devices and AT-MIO-16DE-10 to make up larger ports. For example, with the DIO-96 you can program ports 0, 3, 9, and 10 to make up a 32-bit handshaking port, or program all eight ports to make up a 64-bit handshaking port. Refer to [Digital I/O Application Tips](#) section and the DIG_SCAN_Setup function description of the *Traditional NI-DAQ C Reference Help* for more details.

653X Device Groups

On the 653X devices, you can assign ports 0 through 3 (referring to ports DIOA through DIOD) to one of two groups for handshaking. These groups are referred to as group 1 and group 2. Group 1 uses handshake lines [REQ1](#) and [ACK1](#). Group 2 uses handshake lines REQ2 and ACK2. The group

senses the REQ line. An active REQ signal is an indication that the group must perform a read or write. The group drives the ACK line. After the group has performed a read or write, it drives the ACK line to its active state. Refer to your device user manual for more information on the handshaking signals.

A group can be 8, 16, or 32 bits wide. An 8-bit group can be port 0, 1, 2, or 3. A 16-bit group can be ports 0 and 1 or ports 2 and 3. A 32-bit group is all four ports.

After you have assigned ports to a group, the group acts as a single entity controlling 8, 16, or 32 digital lines simultaneously. The group controls handshaking of that port. These ports are then read from or written to simultaneously by writing or reading 8 or 16 bits at one time from the group.

You can configure the groups for various handshake configurations. The configuration choices include a handshaking protocol, inverted or non-inverted ACK and REQ lines, and a programmed transfer settling time.

Note Implement buffered digital I/O via the `DIG_BLOCK` functions described in detail in the *Traditional NI-DAQ C Reference Help*.

PCI-6115, PCI-6120, and 673X Device Groups

On the PCI-6115, PCI-6120, and 673X devices, port 0 can be broken into two smaller groups. These groups are referred to as group 1 and group 2. One group is configured as an input group and the other is configured as an output group.

Because these devices only have one digital port, a group can consist of any combination of digital lines 0–7. For example, group 1 can be configured as an input group containing lines 0–4 and group 2 as an output group containing lines 5–7. Alternatively, group 1 can be configured as an output group containing lines 1, 3, 5, and 7, and group 2 as an input group containing lines 0, 2, 4, and 6. A portion of the eight available lines can also be configured for group operations, with the remaining unused lines configured for immediate digital operations. However, both groups cannot be configured for input or output at the same time.

Although a group can consist of non-contiguous lines, there is no logical grouping of the lines, and an 8-bit value is still passed from the input function or returned from the output function. For example, if a group is configured for output with lines 0, 1, 2, and 4, and the group is to be written with all ones, the hex value of 0x17 is passed to the function instead of 0xFF.

Group operations are buffered operations only, which means immediate digital operations are not possible with these devices using handshaking. Because all group operations are buffered, there is no support for a status operation indicating when an input operation has been latched to or an output operation latched from the digital lines. Instead, group operations are done from a buffer. In the case of digital output operations, values are written to a buffer and latched onto the digital lines when the appropriate edge from a clock signal is detected. For digital input operations, values are latched from the digital lines to the buffer when the appropriate edge of the clock signal is detected. Either a rising edge or a falling edge of the clock signal can be specified for latching the values. The clock source can be a timing signal used internally or generated external to the board, and it must be routed to one of the RTSI lines.

Digital I/O Functions

The digital I/O (DIG) functions perform nonhandshaked digital line and port I/O.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

DIG_In_Line	Returns the digital logic state of the specified digital input line in the specified port.
DIG_In_Prt	Returns digital input data from the specified digital I/O port.
DIG_Line_Config	Configures the specified line on a specified port for direction (input or output).
DIG_Out_Line	Sets or clears the specified digital output line in the specified digital port.
DIG_Out_Prt	Writes digital output data to the specified digital port.
DIG_Prt_Config	Configures the specified port for direction (input or output).
DIG_Prt_Status	Returns a status word indicating the handshake status of the specified port.

Group Digital I/O Functions

The Group Digital I/O (DIG_Block, DIG_Grp, and DIG_SCAN) functions perform handshaked I/O on groups of ports.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

DIG_Block_Check	Returns the number of items remaining to be transferred after a DIG_Block_In or DIG_Block_Out call.
DIG_Block_Clear	Halts any ongoing asynchronous transfer, allowing another transfer to be initiated.
DIG_Block_In	Initiates an asynchronous data transfer from the specified group to memory.
DIG_Block_Out	Initiates an asynchronous data transfer from memory to the specified group.
DIG_Block_PG_Config	Enables or disables the pattern generation mode of buffered digital I/O.
DIG_Grp_Config	Configures the specified group for port assignment, direction (input or output), and size.
DIG_Grp_Mode	Configures the specified group for handshake signal modes.
DIG_Grp_Status	Returns a status word indicating the handshake status of the specified group.
DIG_In_Grp	Reads digital input data from the specified digital group.
DIG_Out_Grp	Writes digital output data to the specified digital group.
DIG_SCAN_Setup	Configures the specified group for port assignment, direction (input or output), and size.

<code>DIG_Trigger_Config</code>	Enables or disables the trigger mode of buffered digital I/O to indicate when to start and stop the data acquisition.
---------------------------------	---

Double-Buffered Digital I/O Functions

The double-buffered digital I/O (`DIG_DB`) functions perform double-buffered operations during Group Digital I/O operations.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

<code>DIG_DB_Config</code>	Enables or disables double-buffered digital transfer operations and sets the double-buffered options.
<code>DIG_DB_HalfReady</code>	Checks whether the next half buffer of data is available during a double-buffered digital block operation. You can use <code>DIG_DB_HalfReady</code> to avoid the possible waiting period that can occur because <code>DIG_DB_Transfer</code> waits until the data can be transferred before returning.
<code>DIG_DB_Transfer</code>	For an input operation, <code>DIG_DB_Transfer</code> waits until Traditional NI-DAQ can transfer half the data from the buffer being used for double-buffered digital block input to another buffer, which is passed to the function. For an output operation, <code>DIG_DB_Transfer</code> waits until Traditional NI-DAQ can transfer the data from the buffer passed to the function to the buffer being used for double-buffered digital block output. You can execute <code>DIG_DB_Transfer</code> repeatedly to read or write sequential half buffers of data.

Digital Change Notification Functions

The Digital Change Notification functions provide messaging for lines and ports on the 652X devices. For other boards such as the DIO-24, the `Config_DAQ_Event_Message` function handles event messaging.

`DIG_Change_Message_Config`

Configures 652X devices to detect rising or falling edges on input lines and to notify you by generating a message.

`DIG_Change_Message_Control`

Controls the change notification operation of the digital input lines on 652X devices.

Digital Filtering Function

The Digital Filtering function provides signal conditioning to filter the inputs of 652X devices.

`DIG_Filter_Config`

Configures filtering for the input lines on 652X devices.

Digital Change Notification Applications with 652X Devices

Digital change notification applications automatically detect changes on input lines and notify you or your software by message. These applications may use digital filtering to eliminate signals that may trigger unwanted change notification. Digital filtering can be used alone to condition and debounce input data.

Figure 3-18 illustrates the series of calls needed for change notification on the input data. Figure 3-19 illustrates the series of calls needed for filtering the input data without change notification. Only 652X devices can execute change notification and filtering applications using these functions.

Digital Change Detection Applications with 653X Devices

For change detection on the 653X, refer to the `DIG_Block_PG_Config` function in the function reference. For message generation on the 653X and many other devices, refer to the `Config_DAQ_Event_Message` function in the function reference.

Figure 3-18. Basic Digital Change Notification

To configure change notification, call `DIG_Change_Message_Config`. With `DIG_Change_Message_Config`, you can configure individual digital lines for rising, falling, or rising and falling edge detection. Call `DIG_Filter_Config` to enable filtering on some or all of the lines.

The next step is to start change detection messaging by calling the `DIG_Change_Message_Control` function with the start control code.

To stop change notification, call `DIG_Change_Message_Control` with the stop control application. These steps form the basis of a basic digital change notification application.

Figure 3-19. Basic Digital Filtering of Input Data Application

The first step is to call `DIG_Filter_Config`, which enables filtering on the specified lines. Next, you can configure either the ports or the lines. For the 652X devices, configuring the ports by calling `DIG_Prt_Config` is optional, because the ports have fixed directions. `DIG_Line_Config` is also optional because the lines within the ports have fixed directions.

The next step is to call `DIG_In_Port` to read data from an input port. Call `DIG_In_Line` to read a bit from a line. The final step is to loop back if more data is to be read.

Digital I/O Application Tips

This section gives a basic explanation of how to construct an application using the digital input and output functions. The flowcharts are a quick reference for constructing potential applications from the Traditional NI-DAQ function calls.

Handshaking Versus No-Handshaking Digital I/O

Digital ports can output or input digital data in two ways. The first is to immediately read or write data to or from the port. This type of digital I/O is called no-handshaking mode. The second method is to coordinate digital data transfers with another digital port. The second method is called digital I/O with handshaking. With handshaking, you use dedicated transmission lines to ensure that data on the receiving end is not overwritten with new data before it is read from the input port.

Traditional NI-DAQ supports both handshaking and no-handshaking modes. The application outlines within this section explain the use of both modes where they apply.

Digital Port I/O Applications

Digital port I/O applications use individual digital ports to input or output digital data. In addition, the applications input or output data points on an individual basis.

You can configure individual port transfers for handshaking or no-handshaking. All AT devices with digital I/O ports can use no-handshaking digital port I/O. DIO-24, 6025E devices, AT-MIO-16DE-10, and DIO-96 devices can also execute handshaking digital I/O for using the port I/O functions.

Figure 3-20 illustrates the series of calls for digital port I/O applications with handshaking. Figure 3-21 illustrates the series of calls for digital port I/O applications without handshaking.

Figure 3-20. Basic Port Input or Output Application with Handshaking

Figure 3-21. Basic Port Input or Output Application without Handshaking

The first step is to call `DIG_Prt_Config`, with which you configure the individual digital ports for input or output and enable handshaking.

If handshaking is disabled, do not check the port status. If handshaking is enabled, call `DIG_PRT_Status` to determine if an output port is ready to output a new data point, or if an input port has latched new data.

The third step is to input or output the data point. Call `DIG_In_Prt` to read data from an input port. Call `DIG_Out_Prt` to write data to an output port.

The final step is to loop back if more data is to be input or output. These four steps form the basis of a simple digital port I/O application.

Digital Line I/O Applications

Digital line I/O applications are similar to digital port I/O applications, except that digital line I/O applications input or output data on a bit-by-bit basis rather than by port. The digital line I/O can only transfer data in no-handshaking mode.

Figure 3-22 is a flowchart outlining the basic line I/O application.

Figure 3-22. Basic Line Input or Output Application

First, configure the digital lines for input or output. You can program 653X devices, PCI-6703, PCI-6704, PXI-6703, PXI-6704, 671X, 673X, and E Series devices on an individual line basis. To do this, call `DIG_Line_Config`. You must configure all other devices on a port-by-port basis. As a result, you must configure all lines within a port for the same direction. Call `DIG_Prt_Config` to configure a port for input or output. For the 652X devices it is not necessary to configure a port or line since the line direction is preconfigured.

The next step is to call `DIG_In_Line` or `DIG_Out_Line` to output or input a bit from or to the line. The final step is to loop back until NI-DAQ has transferred all of the data.

Digital Group I/O Applications

Digital group I/O applications use one or more digital ports as a single group to input or output digital information, except for the PCI-6115, PCI-6120, and 673X devices, which can create groups smaller than the port size for digital operations.

Figure 3-23 is a flowchart for group digital applications that handshake one point at a time. Only the 653X devices can execute group input or output one point at a time.

Figure 3-23. Simple Digital Group Input or Output Application

At the start of your application, call `DIG_Grp_Config` to configure the individual digital ports as a group. After the ports are grouped, call `DIG_Grp_Mode` (second step of Figure 3-23) to alter the handshaking

mode of the 653X devices. The various handshaking modes and the default settings are explained in the `DIG_Grp_Mode` function description.

The next step in your application is to check if the port is ready for a transfer (third step of Figure 3-23). To do this, call `DIG_Grp_Status`. If the group status indicates it is ready, call `DIG_Out_Grp` or `DIG_In_Grp` to transfer the data to or from the group.

The final step of the flowchart is to loop back until all of the data has been input or output.

Digital Group Block I/O Applications

Traditional NI-DAQ also contains group digital I/O functions, which operate on blocks of data. Figure 3-24 outlines the basic steps for applications that use block I/O.

Figure 3-24. Digital Block Input or Output Application

Note The 653X, DIO-24, 6025E devices, AT-MIO-16DE-10, and DIO-96 all can perform group block operations. However, the DIO-24, 6025E devices, AT-MIO-16DE-10, and DIO-96 have special wiring requirements for groups larger than one port. The wiring for both the input and output cases for these devices is explained in the `DIG_SCAN_Setup` function description. No additional wiring is necessary for the 653X devices.

The first step for a group block I/O application is to call `DIG_Grp_Config` or `DIG_SCAN_Setup` to configure individual ports as a group. Call `DIG_Grp_Config` if you have a 653X, PCI-6115, PCI-6120, or 673X device. Call `DIG_SCAN_Setup` for all other devices. The DIO-32F is restricted to group sizes of two and four ports for block I/O.

If you are using a 653X device, you can alter the handshaking mode of the group by calling `DIG_Grp_Mode`. For the 653X, PCI-6115, PCI-6120, and 673X, you can perform digital pattern generation by calling `DIG_Block_PG_Config`, as shown in Figure 3-24. Pattern generation is simply reading in or writing out digital data at a fixed rate. This is the digital equivalent of analog waveform generation. To enable pattern generation, call `DIG_Block_PG_Config` as shown in Figure 3-24. You cannot handshake with pattern generation, so do not connect any handshaking lines. Refer to the explanation of pattern generation in the [Pattern Generation I/O with 653X, PCI-6115, PCI-6120, and 673X Devices](#) section for more information.

The next step for your application, as illustrated in Figure 3-25, is to call `DIG_Block_In` or `DIG_Block_Out` to start the data transfer.

After you start the operation, you can call `DIG_Block_Check` to get the current progress of the transfer. If the block operation completes prior to a `DIG_Block_Check` call, `DIG_Block_Check` automatically calls `DIG_Block_Clear`, which performs cleanup work.

The final step of a digital block operation is to call `DIG_Block_Clear`. `DIG_Block_Clear` performs the necessary cleanup work after a digital block operation. You must call this function explicitly if `DIG_Block_Check` did not already call `DIG_Block_Clear`.

Note `DIG_Block_Clear` halts any ongoing block operation. Therefore, call `DIG_Block_Clear` only if you are certain the block operation has completed or you want to stop the current operation.

Figure 3-25. Double-Buffered Block Operation

The first step for an application is to call `DIG_Grp_Config` to configure individual ports as a group. Although the steps have been left out of the diagram, you can alter the handshaking mode and enable pattern generation as shown in Figure 3-24, and explained in the [Digital Group Block I/O Applications](#) section. Next, enable double buffering by calling `DIG_DB_Config` (second step of Figure 3-25). To start the digital block input or output, call `DIG_Block_In` or `DIG_Block_Out`.

After the operation has started, you can perform unlimited transfers to or from the circular buffer. Input operations transfer new data from the digital buffer for storage or processing. Output operations transfer new data to the digital buffer for output.

To transfer to or from the circular buffer, call the `DIG_DB_Transfer` function. After you call the function, Traditional NI-DAQ waits until it can transfer the data before returning to the application. To avoid the waiting period, call `DIG_DB_HalfReady` to determine if Traditional NI-DAQ can make the transfer immediately. If `DIG_DB_HalfReady` indicates that Traditional NI-DAQ is not ready for a transfer, your application can do other processing and check the status later.

After the final transfer, you can call `DIG_Block_Check` to get the current progress of the transfer. For example, if you are using double-buffered output, Traditional NI-DAQ requires some time after the final transfer to actually output the data. In addition, if Traditional NI-DAQ completes the block operation prior to a `DIG_Block_Check` call, `DIG_Block_Check` automatically calls `DIG_Block_Clear` to perform cleanup work.

The final step of a double-buffered block operation is to call `DIG_Block_Clear`, which performs the necessary cleanup work after a digital block operation. You must explicitly call this function if `DIG_Block_Check` did not already call it.

Note `DIG_Block_Clear` halts any ongoing block operation. Therefore, call `DIG_Block_Clear` only if you are certain the block operation is complete or if you want to stop the current operation.

Pattern Generation I/O with 653X, PCI-6115, PCI-6120, and 673X Devices

Use pattern generation for clocked digital I/O when you have a group that is written to or read from based on the output of a counter. The `DIG_Block_PG_Config` function enables the pattern generation mode of digital I/O. When pattern generation is enabled, a subsequent

DIG_Block_In or DIG_Block_Out call automatically uses this mode. Each group for the 653X devices has its own onboard counter so that each can simultaneously run in this mode at different rates. Use an external counter by connecting its output to the appropriate REQ pin at the I/O connector. For an input group, pattern generation is analogous to a data acquisition operation, but instead of reading analog input channels, Traditional NI-DAQ reads the digital ports. For an output group, pattern generation is analogous to waveform generation, but instead of writing voltages to the analog output channels, Traditional NI-DAQ writes digital patterns to the digital ports.

The 653X, PCI-6115, PCI-6120, and 673X, use DMA to service pattern generation. However, certain buffers require Traditional NI-DAQ to reprogram the DMA controller during the pattern generation. The extra time needed to reprogram increases the minimum request interval (thus decreasing the maximum rate unless you use dual DMA). Refer to Chapter 4, *Traditional NI-DAQ Double Buffering*, for more information.

Double-Buffered I/O

With the double-buffered (DIG_DB) digital I/O functions, you can input or output unlimited digital data without requiring unlimited memory. Double-buffered digital I/O is useful for applications such as streaming data to disk and sending long data streams as output to external devices. For an explanation of double-buffering, refer to Chapter 4, *Traditional NI-DAQ Double Buffering*.

Digital double-buffered output operations have two options. The first option is to stop the digital block operation if old data is ever encountered. This occurs if the DIG_DB_Transfer function calls are not keeping pace with the data input or output rate; that is, new data is not transferred to or from the circular buffer quickly enough. For digital input, this option prevents the loss of incoming data. For digital output, this option prevents erroneous data from being transferred to an external device. If the group is configured for handshaking, an old data stop is only a pause and a call to one of the transfer functions resumes the digital operation. If the group is configured for pattern generation, an old data stop forces you to clear and restart the block operation.

The second option, available only to output groups, is the ability to transfer data that is less than half the circular buffer size to the circular buffer. This option is useful when long digital data streams are being output, but the size of the data stream is not evenly divisible by the size of half of the circular buffer. This option imposes the restriction that the double-buffered digital block output is halted when a partial block of data has been output. This

means that the data from the first call to `DIG_DB_Transfer` with a count less than half the circular buffer size is the last data output by the device.

Notice, however, that enabling either of the double-buffered digital output options causes an artificial split in the digital block buffer, requiring DMA reprogramming at the end of each half buffer. For a group that is configured for handshaking, such a split means that a pause in data transfer can occur while Traditional NI-DAQ reprograms the DMA. For a group configured for pattern generation, this split can cause glitches in the digital input or output pattern (time lapses greater than the programmed period) during DMA reprogramming. Therefore, you should enable these options only if necessary. Both options can be enabled or disabled by the `DIG_DB_Config` function.

Note EISA chaining is disabled if partial transfers of half buffers are enabled.

Counter/Timer Function Group

The Counter/Timer function group contains the General Purpose Counter/Timer (GPCTR) functions. These functions perform a variety of timing I/O and counter operations such as event counting, period and frequency measurement, and single-pulse and pulse-train generation. Refer to your hardware user manual to find out which operations are supported by your device.

Counter/Timer Operation for the GPCTR Functions

Figure 3-26 shows the 16-bit counters available on DSA devices supported by GPCTR functions.

Figure 3-26. 16-bit Counter Block Diagram

Each counter has a SOURCE input, a GATE input, and an output labeled OUT. 24-bit and 32-bit counters also have an AUX/UP_DOWN input, as shown in Figure 3-27.

Figure 3-27. 24-bit and 32-bit Counter Block Diagram

When using a 24-bit or 32-bit counter for event counting, the input signals perform the following functions:

- SOURCE increments or decrements the counter.
- GATE is used to indicate when to start or stop counting intervals or when to save the counter contents in the save register.
- AUX/UP_DOWN controls the direction of the counting. When configured for hardware control of counting direction, the counter counts up when AUX/UP_DOWN is high, and it counts down when AUX/UP_DOWN is low.

When using a counter for pulse generation, the input signals perform the following functions:

- The counter uses SOURCE as a timebase to generate the pulse.
- The user specifies the pulse parameters in terms of periods of the SOURCE input.
- GATE can serve as a trigger signal to generate a pulse after the first active gate edge, or after each active gate edge.

The GATE input can operate in either buffered or non-buffered mode. Buffered measurements are similar to their single measurement counterparts. However, multiple successive measurements are made. The result of each measurement is saved in the Hardware Save Register on each active edge of GATE. A buffered measurement generates a data stream. This data stream is transferred to your computer via DMA or interrupts. The maximum transfer rates for these buffered measurements are system dependent. Non-buffered measurements do not use a buffer. Unbuffered data appears on the OUT output on each active edge of GATE.

General-Purpose Counter/Timer Functions

Use the General-Purpose Counter/Timer (GPCTR) functions with the E Series, 660X, 671X, 673X, and DSA devices. Refer to the GPCTR functions in the *Traditional NI-DAQ C Reference Help* for a detailed description of how to use the GPCTR functions for a variety of applications.

GPCTR_Change_Parameter	Customizes the counter operation to fit the requirements of your application by selecting a specific parameter setting.
GPCTR_Config_Buffer	Assigns the buffer that Traditional NI-DAQ uses for a buffered counter operation.
GPCTR_Control	Controls the operation of the General-Purpose Counter/Timer.
GPCTR_Read_Buffer	Transfers data from the previously assigned buffer during an asynchronous counter operation.
GPCTR_Set_Application	Selects the application for which you use the General-Purpose Counter/Timer. The function description in the <i>Traditional NI-DAQ C Reference Help</i> contains many application tips.
GPCTR_Watch	Monitors the state of the General-Purpose Counter/Timer and its operation.

General-Purpose Counter/Timer Application Tips

The General-Purpose Counter/Timer (GPCTR) functions perform a variety of event counting, time measurement, and pulse and pulse-train generation operations, including buffered operations. When using the GPCTR functions, follow the generic program flow as shown in Figure 3-28.

Figure 3-28. Generic Program Flow for All GPCTR Applications

To select the type of application you want to use, (for example simple event counting, buffered event counting, period measurement, and so on) call the `GPCTR_Set_Application` function with the appropriate application parameter. If the application is buffered, configure a buffer for use during the acquisition using the `GPCTR_Config_Buffer` function. Next, change some of the counter attributes, depending on your type of application by calling `GPCTR_Change_Parameter`. For example, set the counter source to the internal 100 kHz timebase, set the initial value of the counter to 0, or set the output mode of the counter to pulse mode. Arm the counter with the settings you made by calling `GPCTR_Control`.

If you configure the counter to use a start trigger, the counter will not start counting until it receives the start trigger signal. Otherwise, the counter immediately begins counting. Check the status of the counters by using the `GPCTR_Watch` function. If you are doing a continuous buffered operation, read the buffer by calling `GPCTR_Read_Buffer`. When the operation has completed or you want to abort the operation, reset the counter by calling `GPCTR_Control` with appropriate control code.

For more about GPCTR functions, refer to the `GPCTR_Set_Application` function description in the *Traditional NI-DAQ C Reference Help*.

Clocks or Time Counters

NI-TIO based devices have built-in clocks, which are specialized time counters that retrieve current time and timestamp one or more digital triggers. The number of clocks available depends on the number of NI-TIO chips on your device. Most devices have one clock per NI-TIO chip.

Like counters, clocks have gate signals that latch their current value, or time. They can latch a single time or multiple times in a buffer using interrupts or DMA. Unlike counters, clocks have additional hardware that eliminates drift by synchronizing the clocks to a PPS or IRIG-B stream.

Sample Use Cases

The following cases are examples of applications that can use clocks.

Use Case #1

The user records the time of n events with software timing precision.

A user wants to record the time of an external event—for example, when a key is pressed on a keyboard, when a data packet is received by a CAN controller, or when a temperature is read from an AI channel.

The software program flow is as follows:

1. Initialize the clock for this application.
 - Specify the synchronization signal type (none).
 - Specify the initial DHMS value (the default value of DHMS is undefined).
2. Read the clock value (days, hours, minutes, seconds) when the external event happens to determine the time of the event.
3. At the end of the operation, free up any hardware and software resources. After powering up, the clock will run until the power to the TIO ASIC is turned off.

Use Case #2

The user records the time of a single event on two physically distributed data acquisition systems with hardware timing precision.

A user wants to record how a lightning strike at a power grid in city A travels to a grid station in city B. The lightning sensors in both cities produce a TTL pulse upon receiving the lightning bolt in city A.

Another user wants to correlate buffered analog input measurements across distributed data acquisition systems. He connects a GPS receiver to an NI-TIO device on each system and connects the scan clock to the gate input of the clock. The first active edge on the scan clock on each system will record the global time that sample was taken. The user can use the sample rate on each system to calculate the absolute time each sample was taken, assuming sample rates remain constant throughout the experiment.

The software program flow is as follows:

1. Initialize the clock for this application.
 - Specify the synchronization signal source (PFI line, RTSI line).
 - Specify the synchronization method.
 - If source is PPS, read the current time from the GPS receiver via a serial port and set it as the initial DHMS value of the clock, or choose any arbitrary value. Initialization will take about 2 seconds.
 - If source is IRIG-B, simply wait for 2 seconds after programming the hardware. The clock will automatically synchronize to the GPS signal.
 - Specify gate signal source and polarity.
 - Clock value automatically latches upon receiving the first pulse on its gate input.
2. Poll the armed attribute of the clock until it is disarmed (when the external event happens). The clock is always armed in hardware, but the software abstraction of the clock will be unarmed after it latches the first point.
3. Read the clock value (days, hours, minutes, seconds) to determine the time of the external event.
4. At the end of the operation, free up any hardware and software resources. After powering up, the clock will run until the power to the TIO ASIC is turned off.

RTSI Bus Trigger Functions

The Real-Time System Integration (RTSI) Bus Trigger functions connect and disconnect signals over the RTSI bus trigger lines.

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

<code>RTSI_Clear</code>	Disconnects all RTSI bus trigger lines from signals on the specified device.
<code>RTSI_Clock</code>	Connects or disconnects the system clock from the RTSI bus.
<code>RTSI_Conn</code>	Connects a device signal to the specified RTSI bus trigger line.
<code>RTSI_DisConn</code>	Disconnects a device signal from the specified RTSI bus trigger line.
<code>Select_Signal</code>	Connects or disconnects a device signal to a RTSI bus trigger line.

Refer to the *Traditional NI-DAQ C Reference Help* to determine if your device supports RTSI.

RTSI Bus

The RTSI bus is implemented via a 34-pin ribbon cable connector on the AT, PCI E Series, PCI-DSA, 671X, and 673X devices. On PXI DAQ and DSA devices, the RTSI bus is implemented using PXI trigger bus lines. On E Series DAQ devices for FireWire, the RTSI bus is implemented with a 15-pin mini-*DSUB* connector. The RTSI bus has a 7-wire trigger bus. Each device that works with a RTSI bus interface contains a number of useful signals that can be driven onto, or received from, the trigger lines. Each device is equipped with a switch with which an onboard signal is connected to any one of the RTSI bus trigger lines through software control. By programming one device to drive a particular trigger line and another device to receive from the same trigger line, you can hardware connect the two devices. Use the RTSI Bus Trigger functions described in this chapter for this type of programmable signal interconnection between devices.

Through the RTSI bus, you can trigger one device from another device, share clocks and signals between devices, and synchronize devices to the same signals. The RTSI bus also can connect signals on a single device.

To specify the signals on each device that you can connect to the RTSI bus trigger lines, each device signal is assigned a signal code number. Make all references to that signal by using the signal code number in the RTSI bus trigger function calls. The signal codes for each device that can use the RTSI bus trigger lines are outlined later in this section.

Each signal listed in this chapter also has a signal direction. If a signal is listed with a source direction, that signal can drive the trigger lines. If a signal is listed with a receiver direction, that signal must be received from the trigger lines. A bidirectional signal direction means that the signal can act as either a source or a receiver, depending on the application.

E Series, DSA, 660X, 671X, and 673X RTSI Connections

For information regarding signals on the E Series, DSA, 660X, 671X, and 673X devices that you can connect to the RTSI bus, refer to the `Select_Signal` function description in the *Traditional NI-DAQ C Reference Help*.

Note If you have a PXI-DSA board in slot 2 (star trigger controller slot), do not drive any signals on RTSI 6 from other modules in the chassis. You can use other RTSI lines.

The signals EXTUPDATE* and EXTUPD* externally update selected DACs. The EXTUPDATE* signal is shared with the I/O connector. For more information about the AT-AO-6/10 signals, refer to your device user manual.

653X RTSI Connections

The 653X devices (except for the DAQCard-653X) contain eight signals that you can connect to the RTSI bus trigger lines. Table 3-7 shows these signals.

The direction of each signal depends on the function you are performing. Some signals have a different direction when you enable pattern generation using `DIG_Block_PG_Config` than when you leave pattern generation disabled. Make sure that you do not configure a signal as a RTSI receiver when you use that signal as a device output. For example, do not configure the 653X device to receive the REQ1 line from the RTSI bus if you are using internal requests, or if you have made an external connection that drives the REQ1 pin on the I/O connector.

Table 3-7. 653X RTSI Bus Signals

Signal Name	Signal Direction (Pattern Direction)	Signal Direction (Handshaking, No Pattern Generation)	Signal Direction (No Handshaking)	Signal Code
REQ1	Receiver (external requests) or source (internal requests)	Receiver	Receiver	0
REQ2	Receiver (external requests) or source (internal requests)	Receiver	Receiver	1
ACK1	Receiver (STARTTRIG1)	Source	Source	2
ACK2	Receiver (STARTTRIG2)	Source	Source	3
STOPTRIG1	Receiver	Unused	Receiver	4
STOPTRIG2	Receiver	Unused	Receiver	5
PCLK1	Unused	Source (internal clock) or receiver (external clock)	Source	6
PCLK2	Unused	Source (internal clock) or receiver (external clock)	Source	7

REQ1 and REQ2 are request signals generated internally or received from the I/O connector. ACK1 and ACK2 are acknowledge signals used for handshaking mode; in pattern-generation mode, they can carry start trigger signals instead. PCLK1 and PCLK2 are the peripheral clock lines for burst mode. STOPTRIG1 and STOPTRIG2 are used for data acquisition timing. For more information about the 653X signals, refer to the *DIO 653X User Manual*. Find additional explanations of the ACK1, ACK2, STOPTRIG1, and STOPTRIG2 signals in the DIG_Trigger_Config function in the *Traditional NI-DAQ C Reference Help*.

RTSI Bus Application Tips

This section gives a basic explanation of how to construct an application that uses RTSI bus Traditional NI-DAQ functions. Use the flowcharts as a quick reference for constructing potential applications from the Traditional NI-DAQ function calls.

An application that uses the RTSI bus has three basic steps:

1. Connect the signals from the device to the RTSI bus.
2. Execute the work of the application.
3. Disconnect the signals from the RTSI bus. Figure 3-29 illustrates the normal order of RTSI function calls.

Figure 3-29. Basic RTSI Application Calls

Call `RTSI_Clock/RTSI_Conn` to connect the signals. Each completed signal path requires `RTSI_Conn` calls. The first call specifies the device signal to transmit onto a RTSI bus trigger line. The second call specifies the device signal that receives a RTSI bus trigger line. After the signals are connected, you are ready to do the actual work of your application.

After you finish with the RTSI bus, disconnect the device from the bus. To do this, call `RTSI_DisConn/RTSI_Clock` for each connection made. Alternatively, call `RTSI_Clear` to sever all connections from your device to the RTSI bus.

SCXI Functions

Refer to the *Traditional NI-DAQ C Reference Help* to determine which functions your device supports.

`SCXI_AO_Write`

Sets the DAC channel on the SCXI-1124 module to the specified voltage or current output value. You also can use this

function to write a binary value directly to the DAC channel, or to translate a voltage or current value to the corresponding binary value.

SCXI_Cal_Constants

Calculates calibration constants for the particular channel and range or gain using measured voltage/binary pairs. You can use this function with any SCXI analog input or analog output module. The constants can be stored and retrieved from Traditional NI-DAQ memory or the module EEPROM (if your module has an EEPROM). The driver uses the calibration constants to scale analog input data more accurately when you use the `SCXI_Scale` function and output data when you use `SCXI_AO_Write`.

SCXI_Calibrate

Provides a single call calibration for the SCXI-1112, SCXI-1125, SCXI-1520, and SCXI-1540 modules. With the SCXI-1112 and SCXI-1125, calling this function calibrates individual channels. However, with the SCXI-1540, calling this function calibrates every channel. You also use this function to update the actual onboard reference voltage value on the SCXI-1125 EEPROM and to copy calibration constants to the module's default EEPROM load area from another EEPROM area or from Traditional NI-DAQ memory.

SCXI_Calibrate_Setup

Grounds the amplifier inputs of an SCXI-1100, SCXI-1101, SCXI-1122, or SCXI-1141, SCXI-1142, or SCXI-1143 so that you can determine the amplifier offset. You also can use this function to switch a shunt resistor across your bridge circuit to test the circuit. This function supports shunt calibration for the SCXI-1122 module or the SCXI-1121 module with the SCXI-1321 terminal

	block. It also supports shunt calibration for the SCXI-1520 module with the SCXI-1314 terminal block.
<code>SCXI_Change_Channels</code>	Selects a new channel of a multiplexed module that has previously been set up for a single-channel operation using the <code>SCXI_Single_Channel_Setup</code> function.
<code>SCXI_Configure_Connection</code>	Sets the connection type parameter to a specified type on a given channel or all channels on the SCXI-1520 and SCXI-1540 modules. This function also allows programmatic control of external synchronization.
<code>SCXI_Configure_Filter</code>	Sets the specified channel to the assigned filter setting on any SCXI module with programmable filter settings.
<code>SCXI_Get_Chassis_Info</code>	Returns chassis configuration information.
<code>SCXI_Get_Module_Info</code>	Returns configuration information for the assigned SCXI chassis slot number.
<code>SCXI_Get_State</code>	Gets the state of a single channel or an entire port on any digital or relay module.
<code>SCXI_Get_Status</code>	Reads the data in the status register on the specified module. You can use this function with the SCXI-1160 or SCXI-1122 to determine if the relays have finished switching, with the SCXI-1124 to determine if the DACs have settled, with the SCXI-1126 to determine if the module has settled after changing any of its programmable functions (ranges, filter settings, threshold, or hysteresis), or with the SCXI-1102/B/C to determine if the module has settled after changing gains.
<code>SCXI_Load_Config</code>	Loads the SCXI chassis configuration information that you established in MAX.

	Sets the software states of the chassis and modules present to their default states. No changes are made to the hardware states of the SCXI chassis or modules.
<code>SCXI_ModuleID_Read</code>	Reads the Module ID register of the SCXI module in a given slot. The principal difference between this function and <code>SCXI_Get_Module_Info</code> is that <code>SCXI_ModuleID_Read</code> does a hardware read of the module. You can use this function to verify that your SCXI system is configured and communicating properly.
<code>SCXI_MuxCtr_Setup</code>	Enables or disables a DAQ device counter to be used as a multiplexer counter during SCXI channel scanning to synchronize the scan list with the module scan list that Traditional NI-DAQ has downloaded to Slot 0 of the SCXI chassis.
<code>SCXI_Reset</code>	Resets the specified module to its default state. You also can use <code>SCXI_Reset</code> to reset the Slot 0 scanning circuitry or to reset the entire chassis.
<code>SCXI_Scale</code>	Scales an array of binary data acquired from an SCXI channel to voltage.
<code>SCXI_SCAN_Setup</code>	Sets up the SCXI chassis for a multiplexed scanning data acquisition operation that the assigned DAQ device will perform. The function downloads a module scan list to Slot 0 that determines the sequence of scanned modules and how many channels on each module are scanned. This function can program each module with its given start channel, as well as resolve any contention on the SCXibus.
<code>SCXI_Set_Config</code>	Changes the configuration of the SCXI chassis that you established in

	MAX. Sets the software states of the chassis and modules specified to their default states. Does not change the SCXI chassis or module hardware states.
SCXI_Set_Excitation	Sets a specified excitation parameter to a supplied value on a given channel or all channels on the SCXI-1520, SCXI-1530, SCXI-1531, and SCXI-1540 modules.
SCXI_Set_Gain	Sets the specified channel to the given gain or range setting on any SCXI module that works with programmable gain or range settings.
SCXI_Set_Input_Mode	Configures the SCXI-1122 for differential mode or 4-wire mode.
SCXI_Set_State	Sets the state of a single channel or an entire port on any digital or relay module.
SCXI_Set_Threshold	Used to set the high and low threshold values for the SCXI-1126 frequency-to-voltage module.
SCXI_Single_Chan_Setup	Sets up a multiplexed module for a single-channel analog-input operation to be performed by the given DAQ device. Sets the module channel, enables the module output, and routes the module output on the SCXIBus, if necessary. Resolves any contention on the SCXIBus by disabling the output of any module that was previously driving the SCXIBus. You also can use this function to set up to read the temperature sensor on a terminal block connected to the front connector of the module.
SCXI_Strain_Null	Nulls the offset in the specified strain gage on an SCXI-1520 strain gage module by adjusting the internal potentiometers.

<code>SCXI_Track_Hold_Control</code>	Controls the track-and-hold modules track/hold state that you set up for a single-channel operation.
<code>SCXI_Track_Hold_Setup</code>	Establishes the track/hold behavior of a track-and-hold module and sets up the module for either a single-channel or an interval-scanning operation.

SCXI Application Tips

There are three categories of SCXI applications—analog input applications, analog output applications, and digital applications.

Figure 3-30 shows the basic structure of an SCXI application.

Figure 3-30. General SCXIbus Application

The figures in the following sections show the detailed call sequences for different types of SCXI operations. In effect, each of the remaining

flowcharts in this section is an enlargement of the Analog Input Operations, the Analog Output Operations, or the Digital Operations node in Figure 3-30. Refer to the function descriptions in the *Traditional NI-DAQ C Reference Help* for detailed information about each function used in the flowcharts.

You can divide the SCXI analog input applications further into two categories—single-channel applications and channel-scanning applications. The distinction between the two categories is simple—single-channel applications do not involve automatic channel switching by the hardware during an analog input process; channel-scanning applications do.

After you have set up the SCXI system, single-channel applications use the `AI` or the `DAQ` class of functions described earlier in this chapter to acquire the input data. To acquire data from more than one channel, you need multiple `AI` or `DAQ` function calls, and you might need explicit SCXI function calls to change the selected SCXI channel. This specific type of single-channel application is called *software scanning*.

After you have set up the SCXI system, channel-scanning applications use the `SCAN` and `Lab_ISCAN` classes of functions described earlier in this chapter to acquire the input data.

Building Analog Input Applications in Multiplexed Mode

Multiplexed applications require the use of SCXI functions to select the multiplexed channels, select the programmable module features, route signals on the SCXibus, and program Slot 0. After you have set up the SCXI chassis and modules, you can use the `AI`, `DAQ`, `SCAN`, and `Lab_ISCAN` functions to acquire the data either with a plug-in DAQ device. The **channel** parameter that is passed to each of these functions is almost always 0 because the multiplexed output of a module is connected by default to analog input channel 0 of the DAQ device. If you are using a PXI DAQ device with an internal connection to the PXI-1010 or PXI-1011 SCXibus, then `ND_PXI_SC` is the **channel** parameter. When you use multiple chassis, the modules in each chassis are multiplexed to a separate analog input channel. In that case, the **channel** parameters of the `AI`, `DAQ`, `SCAN`, and `Lab_ISCAN` functions should be the DAQ device channel that corresponds to the chassis you want for the operation.

Figure 3-31 shows the function call sequence of a single-channel or software-scanning application using an SCXI-1100, SCXI-1101, SCXI-1102/B/C, SCXI-1104/C, SCXI-1112, SCXI-1120/D, SCXI-1121, SCXI-1122, SCXI-1125, SCXI-1126, SCXI-1141, SCXI-1142, SCXI-1143, SCXI-1520, SCXI-1530, SCXI-1531, or SCXI-1540 module operating in multiplexed mode.

Figure 3-31. Single-Channel or Software-Scanning Operation in Multiplexed Mode

The `SCXI_Single_Chan_Setup` function selects the given channel to appear at the module output. If the given module is not directly cabled to the DAQ device, the function sends the module output on the SCXibus, and then configures the module that *is* cabled to the DAQ device to send the signal present on the SCXibus to the DAQ device.

The `SCXI_Set_Gain` function changes the gain or range of the SCXI-1100, SCXI-1102/B/C, SCXI-1122, SCXI-1125, SCXI-1126, SCXI-1141, SCXI-1142, SCXI-1143, SCXI-1520, SCXI-1530, SCXI-1531, or SCXI-1540 module. The module maintains this gain or range setting until you call the function again to change it. You also can do any other module-specific programming at this point, such as `SCXI_Configure_Filter` or `SCXI_Set_Input_Mode`.

To achieve software scanning, select a different channel on the module using the `SCXI_Change_Chan` function after acquiring data from the channel you want with the AI or DAQ functions. If you want a channel on a different module, call the `SCXI_Single_Chan_Setup` function again to enable the appropriate module outputs and manage the SCXibus signal routing.

Figure 3-32 shows the function call sequence of a single channel or software-scanning application using a Simultaneous Sample and Hold (SSH) module in multiplexed mode.

Figure 3-32. Single-Channel or Software-Scanning Operation Using a Simultaneous Sample and Hold Module in Multiplexed Mode

Notice the similarities between Figure 3-32 and Figure 3-33, which shows the corresponding application in parallel mode. The `SCXI_Track_Hold_Setup` calls and the `SCXI_Track_Hold_Control` calls are the same. In multiplexed mode, however, an `SCXI_Single_Chan_Setup` call is required to select the multiplexed channel and appropriately route the output to the DAQ device. The `SCXI_Change_Chan` call can change the channel on the module either while the module is in hold mode or after the module has been returned to track mode.

Figure 3-33 shows the function call sequence of a channel-scanning application in multiplexed mode. Remember that only the MIO and AI devices work with channel scanning in multiplexed mode. You can use any combination of module types in a scanning operation. If any track-and-hold modules are to be scanned, use interval scanning; if you are using a plug-in DAQ device, the module directly connected to the DAQ device must be one of the SSH modules.

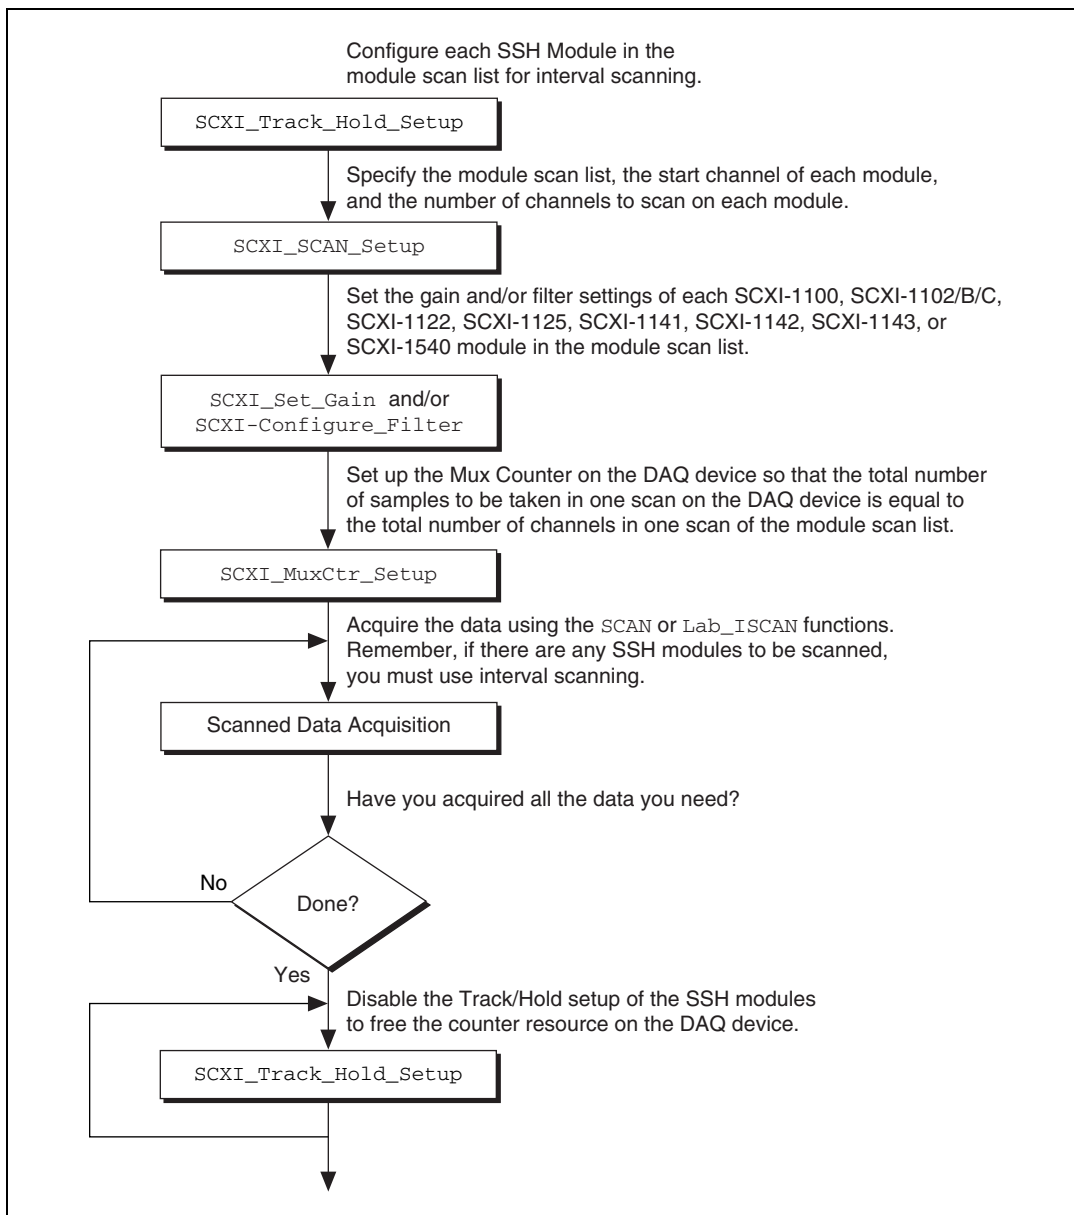

Figure 3-33. Channel-Scanning Operation Using Modules in Multiplexed Mode

If any of the modules to be scanned are SSH modules, you must establish the Track/Hold setup of each one. To synchronize multiple SSH modules, you can configure the module that is receiving the Track/Hold control

signal to send the Track/Hold signal on the SCXIBus so that any other SSH module can use it. The Track/Hold signal can be from either the DAQ device counter or an external source.

The `SCXI_SCAN_Setup` call establishes the module scan list, which Traditional NI-DAQ downloads to Slot 0. Each module is programmed for automatic scanning starting at its given start channel. If you need the SCXIBus during the scan to route the outputs of multiple modules, this function resolves any contention.

In many of the data acquisition function descriptions in the *Traditional NI-DAQ C Reference Help*, the **count** parameter descriptions specify that **count** must be an integer multiple of the total number of channels scanned. In channel-scanning acquisitions in multiplexed mode, the total number of channels scanned is the sum of all the elements in the **numChans** array in the `SCXI_SCAN_Setup` function call.

If any of the modules in the module scan list are SCXI-1100, SCXI-1102/B/C, SCXI-1122, SCXI-1125, SCXI-1126, SCXI-1141, SCXI-1142, SCXI-1143, SCXI-1520, SCXI-1530, SCXI-1531, or SCXI-1540 modules, you can use `SCXI_Set_Gain` to change the gain or range setting on each module. You also can use the `SCXI_Configure_Filter` function for the SCXI-1122, SCXI-1125, SCXI-1126, SCXI-1141, SCXI-1142, SCXI-1143, SCXI-1530, and SCXI-1531, and the `SCXI_Set_Input_Mode` function for the SCXI-1122.

The `SCXI_MuxCtr_Setup` call synchronizes the module scan list with the DAQ device scan list. In most cases (especially when using interval scanning), it is best to ensure that the number of samples Traditional NI-DAQ takes in one pass through the module scan list is the same as the number of samples Traditional NI-DAQ takes in one pass through the DAQ device scan list. Refer to the `SCXI_MuxCtr_Setup` function description in the *Traditional NI-DAQ C Reference Help*.

After you have set up the SCXI chassis and modules, you can perform more than one channel-scanning operation using the `SCAN` or `Lab_ISCAN` functions without reconfiguring the SCXI chassis or modules.

Building Analog Input Applications in Parallel Mode

When you operate the SCXI-1120/D, SCXI-1121, SCXI-1125, SCXI-1126, SCXI-1141, SCXI-1142, and SCXI-1143 modules in parallel mode, you need no further SCXI function calls beyond those shown in Figure 3-34 to set up the modules for analog input operations. After you have initialized and reset the SCXI chassis and modules, you can use the

AI, DAQ, SCAN, or Lab_ISCAN functions with the DAQ device. Remember that the **channel** and **gain** parameters of the AI, DAQ, SCAN, and Lab_ISCAN functions refer to the DAQ device channels and gains.

For example, to acquire a single reading from channel 0 on the module, call the AI_Read function with the **channel** parameter set to 0. The **gain** parameter refers to the DAQ device gain. You then can use the SCXI_Scale function to convert the binary reading to a voltage. The AI_VRead function call is not generally useful in SCXI applications because it does not take into account the gain applied at the SCXI module when scaling the binary reading.

To build a channel-scanning application using the SCXI-1120/D, SCXI-1121, SCXI-1125, SCXI-1126, SCXI-1141, SCXI-1142, or SCXI-1143 in parallel mode, use the SCAN and Lab_ISCAN functions to scan the channels on the DAQ device that correspond to channels on the module you want. For example, to scan channels 0, 1, and 3 on the module using an MIO-16 device, call the SCAN_Op function with the **channel** vector set to {0, 1, 3}. The **gain** vector should contain the MIO and AI device channel gains. After the data is acquired, you can demultiplex it and send the data for each channel to the DAQ_VScale function. Remember to pass the *total gain* to the DAQ_VScale function to obtain the voltage read at the module input.

In many of the data acquisition function descriptions in the *Traditional NI-DAQ C Reference Help*, the **count** parameter descriptions specify that **count** must be an integer multiple of the total number of channels scanned. In channel-scanning acquisitions in parallel mode, the total number of channels scanned is the **numChans** parameter in the SCAN_Setup, SCAN_Op, SCAN_to_Disk, Lab_ISCAN_Start, Lab_ISCAN_Op, or Lab_ISCAN_to_Disk function calls.

The SCXI-1100, SCXI-1101, SCXI-1102/B/C, SCXI-1104/C, SCXI-1112, SCXI-1122, and SCXI-1540 operate in multiplexed mode only.

The SCXI-1140, SCXI-1520, SCXI-1530, and SCXI-1531 modules require the use of SCXI functions to configure and control the Track/Hold state of the module before you can use the AI, DAQ, SCAN, and Lab_ISCAN functions to acquire the data. Figure 3-34 shows the function call sequence of a single-channel (or software-scanning) operation using these modules in parallel mode.

Figure 3-34. Single-Channel or Software-Scanning Operation Using an SSH Module in Parallel Mode

The initial `SCXI_Track_Hold_Setup` call signals the driver that the module is used in a single-channel application, and puts the module into track mode. The first `SCXI_Track_Hold_Control` call latches, or samples, all the module inputs; subsequent AI calls read the sampled

voltages. It is important to realize that all AI operations that occur between the first `SCXI_Track_Hold_Control` call, which puts the module into hold mode, and the second control call, which puts the module into track mode, acquire data that was sampled at the time of the first control call. One or more channels can be read while the module is in hold mode. After you put the module back into track mode, you can repeat the process to acquire new data.

Remember that the **channel** and **gain** parameters of the AI function calls refer to the DAQ device channels and gains. Use the data acquisition channels that correspond to the module channels you want, as described earlier in this section.

Figure 3-35 shows the function call sequence of a channel-scanning application using an SSH module in parallel mode.

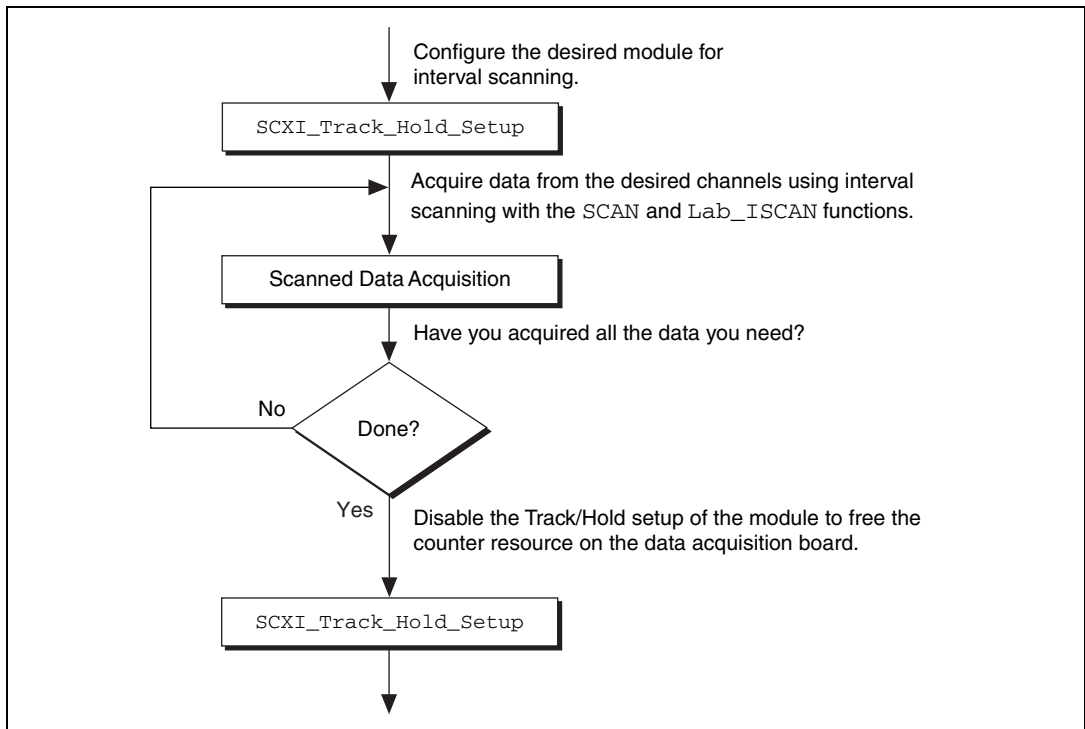

Figure 3-35. Channel-Scanning Operation Using an SSH Module in Parallel Mode

The call sequence is much simpler because the scan interval timer automatically controls the Track/Hold state of the module during the

interval-scanning operation. Remember that only the MIO and AI devices work with channel-scanning using an SSH module.

SCXI Data Acquisition Rates

The settling time of the SCXI modules can affect the maximum data acquisition rates that your DAQ device can achieve. The settling times of the different SCXI modules at each gain setting are listed in Table 3-8 for three different DAQ devices.

The maximum data acquisition rate you can use will be the inverse of the settling time for your SCXI module and DAQ device. For example, if the settling time is listed as 7 μ s, your maximum data acquisition rate will be

$$\frac{1}{7 \mu s} = 143 \text{ kS/s}$$

If you are using a DAQ device with a maximum acquisition rate faster than the AT-MIO-16E-2 (such as the PCI-MIO-16E-1), you should use the settling times and corresponding maximum acquisition rates listed for the AT-MIO-16E-2.

If you are using a DAQ device with a maximum acquisition rate slower than 200 kS/s (such as the PCI-6032E), you should add 1 μ s to the settling time of your DAQ device. The maximum acquisition rate for the PCI-6032E would be

$$\frac{1}{(10 \mu s + 1 \mu s)} = 90.9 \text{ kS/s}$$

If you are using a DAQ device faster than 200 kS/s but slower than the AT-MIO-16E-2 (such as an AT-MIO-64E-3), you can interpolate between the settling times listed for these devices to calculate an appropriate settling time and corresponding maximum data acquisition rate.

Table 3-8. Maximum SCXI Module Settling Times

SCXI Module	Gain	Settling Time Using up to 12-bit, 200 kS/s ¹ Device	Settling Time Using AT-MIO-16E-2 ²	Settling Time Using AT-MIO-16XE-10 (±0.006% Accuracy) ³	Settling Time Using AT-MIO-16XE-10 (±0.0015% Accuracy) ³
SCXI-1100 (no filter)	1 to 100	7 µs	4 µs	10 µs	32 µs
	200	10 µs	5.5 µs	10 µs	33 µs
	500	16 µs	12 µs	25 µs	40 µs
	1,000	50 µs	20 µs	30 µs	76 µs
	2,000	50 µs	25 µs	30 µs	195 µs
SCXI-1102/B/C, SCXI-1104/C, SCXI-1112	all gains	7 µs	3 µs	10 µs	—
SCXI-1120, SCXI-1120D, SCXI-1125	all gains	7 µs	3 µs	10 µs	20 µs
SCXI-1121	all gains	7 µs	3 µs	10 µs	20 µs
SCXI-1122	all gains	10 ms	10 ms	10 ms	10 ms
SCXI-1126	all gains or ranges	7 µs	3 µs	10 µs	20 µs
SCXI-1140	all gains	7 µs	3 µs	10 µs	20 µs
SCXI-1141, SCXI-1142, SCXI-1143, SCXI-1520, SCXI-1540	all gains	7 µs	3 µs	10 µs	20 µs

¹ Includes effects of a 12-bit, 200 kS/s device with 1 m SCXI cable assembly.

² Includes effects of AT-MIO-16E-2 with 1 or 2 m SCXI cable assembly.

³ Includes effects of AT-MIO-16XE-10 with 1 or 2 m SCXI cable assembly.

Note: If you are using remote SCXI, the maximum data acquisition rate also depends on the serial baud rate used. For more information, refer to your SCXI user manual.

The filter setting on the SCXI-1100 and the SCXI-1122 dramatically affects settling time. Refer to the *Specifications* appendix in your SCXI module user manual for details.

Note The SCXI-1122 uses relays to switch the input channels. The module requires 10 ms to settle when the relays switch, so the sampling rate in a channel scanning operation cannot exceed 100 Hz. If you want to take many readings from each channel and average them to reduce noise, you should use the single-channel or software-scanning method shown in Figure 3-34 instead of the channel-scanning method shown in Figure 3-35.

This means you select one channel on the module, acquire many samples on that channel using the DAQ functions, select the next channel, and so on. This increases the lifetime of your module relays. When you have selected a particular channel, you can use the fastest sample rate your DAQ device supports with the DAQ functions.

Analog Output Applications

Using the SCXI-1124 analog output module with the Traditional NI-DAQ functions is simple. Call the `SCXI_AO_Write` function to write the voltages you want to the module DAC channels. You can use the `SCXI_Get_Status` function to determine when the DAC channels have settled to their final analog output voltages.

To calculate new calibration constants for `SCXI_AO_Write` to use for the voltage to binary conversion instead of the factory calibration constants that are shipped in the module EEPROM, refer to the `SCXI_Cal_Constants` function description.

Digital Applications

If you configured your digital or relay modules for multiplexed mode, use the `SCXI_Set_State` and `SCXI_Get_State` functions to access your digital or relay channels.

If you are using the SCXI-1160 module, you might want to use the `SCXI_Get_Status` function after calling the `SCXI_Set_State` function. `SCXI_Get_Status` tells you when the SCXI-1160 relays have finished switching.

If you are using the SCXI-1162/HV module, `SCXI_Get_State` reads the module input channels. For the other digital and relay modules, `SCXI_Get_State` returns a software copy of the current state that Traditional NI-DAQ maintains. However, if you are using the SCXI-1163/R in parallel mode, `SCXI_Get_State` reads the hardware states.

If you are using the SCXI-1162/HV or SCXI-1163/R in parallel mode, you can use the SCXI functions as described above, or you can call the `DIG_In_Prt` and `DIG_Out_Prt` functions using the correct DAQ device port numbers that correspond to the SCXI module channels. The MIO and AI devices cannot use the SCXI-1162/HV or the SCXI-1163/R in parallel mode.

Traditional NI-DAQ Double Buffering

This chapter describes using double-buffered data acquisitions with Traditional NI-DAQ. This chapter applies to counter operations; however, you can read samples of any size.

Overview

Conventional data acquisition software techniques, such as single-buffered data acquisition, work well for most applications. However, more sophisticated applications involving larger amounts of data at higher rates require more advanced techniques for managing the data. One such technique is double buffering. National Instruments uses double-buffering techniques in its driver software for continuous, uninterrupted input or output of large amounts of data.

This chapter discusses the fundamentals of double buffering, including specific information on how the Traditional NI-DAQ double-buffered functions work.

Note Input and output refer to both digital and analog operations in this chapter.

Single-Buffered versus Double-Buffered Data

The most common method of data buffering found in conventional driver software is single buffering. In single-buffered input operations, a fixed number of samples are acquired at a specified rate and transferred into computer memory. After the memory buffer stores the data, the computer can analyze, display, or store the data to the hard disk for later processing. Single-buffered output operations output a fixed number of samples from computer memory at a specified rate. After outputting data, the buffer can be updated with new or freed data.

Single-buffered operations are relatively simple to implement, can usually take advantage of the full hardware speed of the DAQ device, and are very

useful for many applications. The major disadvantage of single-buffered operations is that the amount of data that can be input or output is limited to the amount of free memory available in the computer.

In double-buffered input operations, the data buffer is configured as a circular buffer. For input operations, the DAQ device fills the circular buffer with data. When the end of the buffer is reached, the device returns to the beginning of the buffer and fills it with data again. This process continues *indefinitely* until it is interrupted by a hardware error or cleared by a function call.

Double-buffered output operations also use a circular buffer. In this case, however, the DAQ device retrieves data from the circular buffer for output. When the end of the buffer is reached, the device begins retrieving data from the beginning of the buffer again.

Unlike single-buffered operations, double-buffered operations reuse the same buffer and are therefore able to input or output an infinite number of data points without requiring an infinite amount of memory. However, for double buffering to be useful, there must be a means by which to access the data for updating, storing, and processing. The next two sections explain how to access the data for double-buffered input and output operations.

Double-Buffered Input Operations

The data buffer for double-buffered input operations is configured as a circular buffer. In addition, Traditional NI-DAQ logically divides the buffer into two equal halves (no actual division exists in the buffer). By dividing the buffer into two halves, Traditional NI-DAQ can coordinate user access to the data buffer with the DAQ device. The coordination scheme is simple—Traditional NI-DAQ copies data from the circular buffer in sequential halves to a transfer buffer you create. You can process or store the data in the transfer buffer however you choose.

Figure 4-1 illustrates a series of sequential data transfers.

**Figure 4-1.** Double-Buffered Input with Sequential Data Transfers

The double-buffered input operation begins when the DAQ device starts writing data into the first half of the circular buffer (Figure 4-1a). After the device begins writing to the second half of the circular buffer, Traditional NI-DAQ can copy the data from the first half into the transfer buffer (Figure 4-1b). You then can store the data in the transfer block to disk or process it according to your application needs. After the input device has filled the second half of the circular buffer, the device returns to the first half of the buffer and overwrites the old data. Traditional NI-DAQ can now copy the second half of the circular buffer to the transfer buffer (Figure 4-1c). The data in the transfer buffer is again available for use by your application. The process can be repeated endlessly to produce a continuous stream of data to your application. Notice that Figure 4-1d is equivalent to the step in Figure 4-1b and is the start of a two-step cycle.

Potential Setbacks

The double-buffered coordination scheme is not flawless. An application might experience two possible problems with double-buffered input. The first is the possibility of the DAQ device overwriting data before Traditional NI-DAQ has copied it to the transfer buffer. This situation is illustrated by Figure 4-2.

Figure 4-2. Double-Buffered Input with an Overwrite Before Copy

Notice that in Figure 4-2b, Traditional NI-DAQ has missed the opportunity to copy data from the first half of the circular buffer to the transfer buffer while the DAQ device is writing data to the second half. As a result, the DAQ device begins overwriting the data in the first half of the circular buffer before Traditional NI-DAQ has copied it to the transfer buffer (Figure 4-2c). To guarantee uncorrupted data, Traditional NI-DAQ must wait until the device finishes overwriting data in the first half before copying the data into the transfer buffer. After the device has begun to write to the second half, Traditional NI-DAQ copies the data from the first half of the circular buffer to the transfer buffer (Figure 4-2d).

For the previously described situation, Traditional NI-DAQ returns an overwrite before copy warning (**overWriteError**). This warning indicates that the data in the transfer buffer is valid, but some earlier input data has been lost. Subsequent transfers will not return the warning as long as they keep pace with the DAQ device as in Figure 4-1.

The second potential problem occurs when an input device overwrites data that Traditional NI-DAQ is simultaneously copying to the transfer buffer. Traditional NI-DAQ returns an overwrite error (**overWriteError**) when this occurs. The situation is presented in Figure 4-3.

Figure 4-3. Double-Buffered Input with an Overwrite

In Figure 4-3b, Traditional NI-DAQ has started to copy data from the first half of the circular buffer into the transfer buffer. However, Traditional NI-DAQ is unable to copy the entire half before the DAQ device begins overwriting data in the first half of the buffer (Figure 4-3c). Consequently, data copied into the transfer buffer might be corrupted; that is, it might contain both old and new data points. Future transfers will execute normally as long as neither of the problem conditions re-occur.

Double-Buffered Output Operations

Double-buffered output operations are similar to input operations. The circular buffer is again logically divided into two halves. By dividing the buffer into two halves, Traditional NI-DAQ can coordinate user access to the data buffer with the DAQ device. The coordination scheme is simple—Traditional NI-DAQ copies data from a transfer buffer you create to the circular buffer in sequential halves. The data in the transfer buffer can be updated between transfers.

Figure 4-4 illustrates a series of sequential data transfers.

Figure 4-4. Double-Buffered Output with Sequential Data Transfers

The double-buffered output operation begins when the output device begins outputting data from the first half of the circular buffer (Figure 4-4a). After the device begins retrieving data from the second half of the circular buffer, Traditional NI-DAQ can copy the prepared data from the transfer buffer to the first half of the circular buffer (Figure 4-4b). Your application then can update the data in the transfer buffer. After the output device is finished

with the second half of the circular buffer, the device returns to the first half buffer and begins outputting updated data from the first half. Traditional NI-DAQ can now copy the transfer buffer to the second half of the circular buffer (Figure 4-4c). The data in the transfer buffer is again available for update by your application. The process can be repeated endlessly to produce a continuous stream of output data from your application. Notice that Figure 4-4d is equivalent to the step in Figure 4-4b and is the start of a two-step cycle.

Potential Setbacks

Like double-buffered input, double-buffered output has two potential problems. The first is the possibility of the output device retrieving and outputting the same data before Traditional NI-DAQ has updated the circular buffer with new data from the transfer buffer. This situation is illustrated by Figure 4-5.

Notice that in Figure 4-5b, Traditional NI-DAQ has missed the opportunity to copy data from the transfer buffer to the first half of the circular buffer while the output device is retrieving data from the second half. As a result, the device begins to output the original data in the first half of the circular buffer before Traditional NI-DAQ has updated it with data from the transfer buffer (Figure 4-5c). To guarantee uncorrupted output data, Traditional NI-DAQ is forced to wait until the device finishes retrieving data from the first half before copying the data from the transfer buffer. After the device has begun to output the second half, Traditional NI-DAQ copies the data from the transfer buffer to the first half of the circular buffer (Figure 4-5d).

Figure 4-5. Double-Buffered Output with an Overwrite before Copy

For this situation, Traditional NI-DAQ returns an overwrite before a copy warning (**overWriteError**). This warning indicates that the device has output old data but the data was uncorrupted during output. Subsequent transfers will not return the warning as long as they keep pace with the output device as in Figure 4-4.

The second potential problem is when an output device retrieves data that Traditional NI-DAQ is simultaneously overwriting with data from the transfer buffer. Traditional NI-DAQ returns an overwrite error (**overWriteError**) when this occurs. The situation is presented in Figure 4-6.

Figure 4-6. Double-Buffered Output with an Overwrite

In Figure 4-6b, Traditional NI-DAQ has started to copy data from the transfer buffer to the first half of the circular buffer. However, Traditional NI-DAQ is unable to copy all of the data before the output device begins retrieving data from the first half (Figure 4-6c). Consequently, device data output might be corrupted; it might contain both old and new data points. Future transfers will execute normally as long as neither of these problem conditions occur again.

Double-Buffered Functions

Double-buffered functions exist for analog input (DAQ), analog output (WFM), digital input/output (DIG), and general-purpose counter (GPCTR) operations. This section explains what each of the functions do and the order in which you should call them.

Double Buffer Configuration Functions

The Double Buffer Configuration functions enable and disable double buffering for input and output operations, and you can select double-buffering options if any are available.

The configuration functions are as follows:

- `DAQ_DB_Config`
- `WFM_DB_Config`
- `DIG_DB_Config`
- `GPCTR_Change_Parameter`

For analog input operations, call `DAQ_DB_Config` prior to calling `DAQ_Start`, or a `SCAN_Start` to enable or disable double buffering.

For waveform operations, call `WFM_DB_Config` prior to calling `WFM_Load` to enable or disable double buffering.

For digital block input and output operations, call `DIG_DB_Config` prior to calling `DIG_Block_In`, or `DIG_Block_Out` to enable or disable double buffering.

For counter operations, before calling `GPCTR_Control` to start your counter, call `GPCTR_Change_Parameter` to enable or disable continuous buffering (with `ND_Double`). Counters transfer their data continuously, not in half buffers.

Double Buffer Transfer Functions

After a double-buffered operation begins, the Double Buffer Transfer functions transfer data to or from a circular buffer. The direction of the transfer depends on the direction of the double-buffered operations. Along with copying data, the Double Buffer Transfer functions also check for possible errors during the transfer.

For input operations, `DB_Transfer` copies data from alternating halves of the circular input buffer to the transfer buffer. For output operations, `DB_Transfer` copies data from the buffer passed to the function to alternating halves of the circular output buffer. The function might return an overwrite before a copy warning or an overwrite error (**overWriteError**) if a problem occurs during the transfer.

Note Waveform transfer functions do not detect overwrite before copy or overwrite errors.

The `DB_Transfer` functions for `DAQ`, `WFM`, `DIG`, and `GPCTR` are synchronous for both input and output operations. In other words, when your application calls these functions, Traditional NI-DAQ does not return control to your application until the transfer is complete. As a result, your application might crash if Traditional NI-DAQ cannot complete the

transfer. To avoid this situation, call the `Timeout_Config` function for DAQ, WFM, DIG, and GPCTR prior to starting a double-buffered operation. The timeout configuration function sets the maximum time allocated to complete a synchronous function call for a device. For counter operations, the transfer function takes timeout as one of the parameters, so you do need to call `Timeout_Config` prior to calling the transfer function.

The transfer functions are as follows:

- `DAQ_DB_Transfer`
- `WFM_DB_Transfer`
- `DIG_DB_Transfer`
- `GPCTR_Read_Buffer`

For analog input operations, call `DAQ_DB_Transfer` after starting a double-buffered analog acquisition to perform a double-buffered transfer.

For waveform operations, call `WFM_DB_Transfer` after starting a double-buffered waveform generation to perform a double-buffered transfer.

For digital block input and output operations, call `DIG_DB_Transfer` after starting a double-buffered digital operation to perform a double-buffered transfer.

For counter operations call `GPCTR_Read_Buffer` after starting the operation to transfer a specified portion of the double buffer.

Double Buffer HalfReady Functions

With the Double Buffer HalfReady functions, applications can avoid the delay possible when calling the double buffer transfer function. When you call either of the transfer functions, Traditional NI-DAQ waits until the transfer to or from the circular buffer can be made; that is, the DAQ device is operating on the opposite half of the circular buffer.

The Double Buffer HalfReady functions check if a double buffer transfer can be completed immediately. If the call to Double Buffer HalfReady indicates a transfer cannot be made, your application can do other work and try again later.

The HalfReady functions are as follows:

- `DAQ_DB_HalfReady`
- `WFM_DB_HalfReady`

- `DIG_DB_HalfReady`
- `GPCTR_Read_Buffer`

For analog input operations, call `DAQ_DB_HalfReady`, after starting a double-buffered analog acquisition but prior to calling `DAQ_DB_Transfer`, to check the transfer status of the operation.

For analog output problems, call `WFM_DB_HalfReady`, after starting a double-buffered waveform generation but prior to calling `WFM_DB_Transfer`, to check the transfer status of the operation.

For digital block input and output operations, call `DIG_DB_HalfReady` after starting a double-buffered digital operation but prior to calling `DIG_DB_Transfer`, to check the transfer status of the operation.

For counter operations, call `GPCTR_Read_Buffer` after calling `GPCTR_Control` with a **timeOut** of 0, to check the transfer status of the operation. Counters actually transfer their data in a continuous manner, not a double-buffered manner.

Conclusion

Double buffering is a data acquisition software technique for continuously inputting or outputting large amounts of data with limited available system memory. However, double buffering might not be practical for high-speed input or output applications. The throughput of a double-buffered operation is typically limited by the ability of the CPU to process the data within a given period of time. Specifically, data must be processed by the application at least as fast as the rate at which the device is writing or reading data. For many applications, this requirement depends on the speed and efficiency of the computer system and programming language.

Transducer Conversion Functions

This chapter describes the Traditional NI-DAQ Transducer Conversion functions. Traditional NI-DAQ includes source code for these functions.

The Transducer Conversion functions convert analog input voltages read from thermocouples, *RTDs*, thermistors, and strain gages into temperature or strain units:

<code>RTD_Convert</code>	Supplied single-voltage and voltage-buffer routines convert voltages read from an RTD into resistance and then into temperature in units for Celsius, Fahrenheit, Kelvin, or Rankine.
<code>Strain_Convert</code>	Supplied single-voltage and voltage-buffer routines convert voltages read from a strain gage into measured strain using the appropriate formula for the strain gage bridge configuration used.
<code>Thermistor_Convert</code>	Supplied single-voltage and voltage-buffer routines convert voltages read from thermistors into temperature.
<code>Thermocouple_Convert</code>	Supplied single-voltage and voltage-buffer routines convert voltages read from B-, E-, J-, K-, N-, R-, S-, or T-type thermocouples into temperature in Celsius, Fahrenheit, Kelvin, or Rankine.

Traditional NI-DAQ installs the source files for these functions in the same directories as the example programs. You can cut and paste, include, or merge these conversion routines into your application source files in order to call the routines in your application.

The conversion routines are included in Traditional NI-DAQ as source files rather than driver function calls so that you have complete access to the

conversion formulas. You can edit the conversion formulas or replace them with your own to meet your application's specific accuracy requirements. Comments in the conversion source code simplify the process of making only necessary changes.

A header file for each language (`convert.h` for C/C++, `convert.bas` for Visual Basic) contains the constant definitions used in the conversion routines. Include or merge this header file into your application program.

The transducer conversion routine descriptions apply to all languages.

Function Descriptions

RTD_Convert and RTD_Buf_Convert

These functions convert a voltage or voltage buffer that Traditional NI-DAQ reads from an RTD into temperature.

Parameter Discussion

The **convType** integer indicates whether to use the given conversion formula, or to use a user-defined formula that you have put into the routine.

- 0: The given conversion formula.
- 1: Use a user-defined formula that has been added to the routine.

Iex is the excitation current in amps that was used with the RTD. If a 0 is passed in **Iex**, a default excitation current of 150×10^{-6} A (150 mA) is assumed.

Ro is the RTD resistance in ohms at 0 °C.

A and **B** are the coefficients of the Callendar Van-Düsen equation that fit your RTD.

The **TempScale** integer indicates which temperature units you want your return values to be. Constant definitions for each temperature scale are given in the conversion header file.

- 1: Celsius
- 2: Fahrenheit
- 3: Kelvin
- 4: Rankine

The `RTD_Convert` routine has two remaining parameters—**RTDVolts** is the voltage that Traditional NI-DAQ reads from the RTD, and **RTDTemp** is the return temperature value.

The `RTD_Buf_Convert` routine has three remaining parameters—**numPts** is the number of voltage points to convert, **RTDVoltBuf** is the array that contains the voltages that Traditional NI-DAQ read from the RTD, and **RTDTempBuf** is the return array that contains the temperatures.

Using This Function

The conversion routines first find the RTD resistance by dividing **RTDVolts** (or each element of **RTDVoltBuf**) by **Iex**. The function converts that resistance to a temperature using a solution to the Callendar Van-Düsen equation for RTDs:

$$R_t = R_0[1 + At + Bt^2 + C(t - 100)t^3]$$

For temperatures above 0 °C, the C coefficient is 0 and the equation reduces to a quadratic equation for which we have found the appropriate root. Thus, these conversion routines are accurate only for temperatures above 0 °C.

Your RTD documentation should give you **R₀** and the **A** and **B** coefficients for the Callendar Van-Düsen equation. The most common RTDs are 100 Ω platinum RTDs that either follow the European temperature curve (also known as the DIN EN 60751 standard) or the American curve. The values for **A** and **B** are as follows:

- European Curve (DIN EN 60751):

$$\mathbf{A} = 3.90802 \times 10^{-3}$$

$$\mathbf{B} = -5.80195 \times 10^{-7}$$

$$(\alpha = 3.85 \times 10^{-3}; \partial = 1.492)$$

- American Curve:

$$\mathbf{A} = 3.9784 \times 10^{-3}$$

$$\mathbf{B} = -5.8408 \times 10^{-7}$$

$$(\alpha = 3.92 \times 10^{-3}; \partial = 1.492)$$

Some RTD documentation contains values for α and ∂ , from which you can calculate **A** and **B** using the following equations:

$$\mathbf{A} = \alpha(1 + \partial/100)$$

$$\mathbf{B} = -\alpha\partial/(10,000, 100^2)$$

where α is the temperature coefficient at $T = 0\text{ }^{\circ}\text{C}$.

$$C = -\alpha \beta / 1,000,000$$

where β is a characteristic of your RTD similar to the α and ∂ equation coefficients.

Strain_Convert and Strain_Buf_Convert

These functions convert a voltage or voltage buffer that Traditional NI-DAQ read from a strain gage to units of strain.

Parameter Discussion

The **bridgeConfig** integer indicates in what type of bridge configuration the strain gage is mounted. Figure 5-1 shows all the different bridge configurations and the corresponding values that you should pass in **bridgeConfig**.

Vex is the excitation voltage (in volts) that you used. If the value of **Vex** is 0, a default excitation voltage of 3.333 V is assumed. The SCXI-1121 module provides excitation voltages of 10 V and 3.333 V. The SCXI-1122 module provides an excitation voltage of 3.333 V.

GF is the gage factor of the strain gage.

v is Poisson's Ratio (needed only in certain bridge configurations).

Rg is the strain gage nominal value in ohms.

RL is the lead resistance in ohms. In many cases, the lead resistance is negligible and you can pass a value of 0 for **RL** to the routine. Otherwise, you can measure **RL** to be more accurate.

V_{init} is the unstrained voltage of the strain gage in volts after it is mounted in its bridge configuration. Read this voltage at the beginning of your application and save it to pass to the strain gage conversion routines.

The **Strain_Convert** routine has two remaining parameters—**strainVolts** is the voltage that Traditional NI-DAQ read from the strain gage, and **strainVal** is the return strain value.

The **Strain_Buf_Convert** routine has three remaining parameters—**numPts** is the number of voltage points to convert, **strainVoltBuf** is the array that contains the voltages that Traditional

NI-DAQ read from the strain gage, and **strainValBuf** is the return array that contains the strain values.

Using This Function

The conversion formula used is based solely on the bridge configuration. Figure 5-1 shows the seven bridge configurations supported and the corresponding formulas. For all bridge configurations, Traditional NI-DAQ uses the following formula to obtain V_r :

$$V_r = \frac{\text{strainVolts} - V_{\text{init}}}{V_{\text{ex}}}$$

In the circuit diagrams shown in Figure 5-1, V_{out} is the voltage you measure and pass to the `Strain_Convert` function as the **strainVolts** parameter. In the quarter-bridge and half-bridge configurations, R_1 and R_2 are dummy resistors that are not directly incorporated into the conversion formula. The SCXI-1121 and SCXI-1122 modules provide R_1 and R_2 for a bridge-completion network, if needed. Refer to the *Getting Started with SCXI* user manual for more information on bridge-completion networks and voltage excitation.

Figure 5-1. Strain Gage Bridge Configuration

Thermistor_Convert and Thermistor_Buf_Convert

These functions convert a voltage or voltage buffer read from a thermistor into temperature. Some SCXI terminal blocks have onboard thermistors that you can use to do *cold-junction compensation*.

Parameter Discussion

V_{ref} is the voltage reference you apply across the thermistor circuit in volts. Refer to Figure 5-2. The thermistor on the SCXI terminal blocks has a V_{ref} of 2.5 V.

R_1 is the value of the resistor in series with your thermistor in ohms. Refer to Figure 5-2. The thermistor on the SCXI terminal blocks has an R_1 value of 5,000 Ω .

The **TempScale** integer indicates in which temperature unit you want your return values to be. Constant definitions for each temperature scale are assigned in the conversion header file.

- 1: Celsius
- 2: Fahrenheit
- 3: Kelvin
- 4: Rankine

The `Thermistor_Convert` function has two remaining parameters—**Volts** is the voltage that you read from the thermistor, and **Temperature** is the return temperature value assigned in units determined by **TempScale**.

The `Thermistor_Buf_Convert` function has three remaining parameters—**numPts** is the number of voltage points to convert, **VoltBuf** is the array of voltages that you read from the thermistor, and **TempBuf** is the return array of temperature values assigned in units determined by **TempScale**.

Using This Function

The following equation expresses the relationship between **Volts** and R_t , the thermistor resistance. Refer to Figure 5-2.

$$\text{Volts} = V_{\text{ref}} \left(\frac{R_t}{R_1 + R_t} \right)$$

Solving the previous equation for R_t , we have:

$$R_t = R_1 \left(\frac{\text{Volts}}{(V_{\text{ref}} - \text{Volts})} \right)$$

After this function calculates R_t , the function uses the following equation to convert R_t , the thermistor resistance, to temperature in Kelvin. The function then converts the temperature to the temperature scale you want, if necessary.

$$T = \frac{1}{a + b((1/R_t) + c(1/R_t)^3)}$$

The values used for a , b , and c are given below. If you are using a thermistor with different values for a , b , and c (refer to your thermistor data sheet), you can edit the thermistor conversion routine to use your own a , b , and c values.

$$a = 1.295361\text{E-}3$$

The following equation expresses the relationship between **Volts** and R_t , the thermistor resistance. Refer to Figure 5-2.

$$\text{Volts} = V_{\text{ref}} \left(\frac{R_t}{(R_1 + R_t)} \right)$$

Solving the previous equation for R_t , you have:

$$R_t = R_1 \left(\frac{\text{Volts}}{(V_{\text{ref}} - \text{Volts})} \right)$$

When you calculate R_t , you use the following equation to convert R_t , the thermistor resistance, to temperature in Kelvin. Then convert the temperature to the temperature scale you want, if necessary.

$$T = \frac{1}{a + b((1/R_t) + c(1/R_t)^3)}$$

The values used for **a**, **b**, and **c** are shown below. These values are correct for the thermistors provided on the SCXI terminal blocks. If you are using a thermistor with different values for **a**, **b**, and **c** (refer to your thermistor data sheet), you can edit the thermistor conversion routine to use your own **a**, **b**, and **c** values.

$$\mathbf{a} = 1.295361\text{E-}3$$

$$\mathbf{b} = 2.343159\text{E-}4$$

$$\mathbf{c} = 1.018703\text{E-}7$$

Figure 5-2. Circuit Diagram of a Thermistor in a Voltage Divider

Thermocouple_Convert and Thermocouple_Buf_Convert

These functions convert a voltage or voltage buffer that Traditional NI-DAQ read from a thermocouple into temperature.

Parameter Discussion

The **TCType** integer indicates what type of thermocouple Traditional NI-DAQ used to read the temperature. Constant definitions for each thermocouple type are shown in the conversion header file. You can use the constants that have been defined, or you can pass integer values to the routine.

- 1: E
- 2: J
- 3: K
- 4: R
- 5: S
- 6: T

7: B

8: N

CJCTemp is the temperature in Celsius that Traditional NI-DAQ uses for cold-junction compensation of the thermocouple temperature. If you are using SCXI, most likely this is the temperature that Traditional NI-DAQ read from the temperature sensor on the SCXI terminal block. The AMUX-64T also has a temperature sensor that you can use for this purpose.

The **TempScale** integer indicates in which temperature unit you want your return values to be. Constant definitions for each temperature scale are shown in the conversion header file.

1: Celsius

2: Fahrenheit

3: Kelvin

4: Rankine

The `Thermocouple_Convert` routine has two remaining parameters—**TCVolts** is the voltage that Traditional NI-DAQ read from the thermocouple, and **TCTemp** is the return temperature value.

The `Thermocouple_Buf_Convert` routine has three remaining parameters—**numPts** is the number of voltage points to convert, **TCVoltBuf** is the array that contains the voltages that Traditional NI-DAQ read from the thermocouple, and **TCTempBuf** is the return array that contains the temperatures.

Using This Function

These routines convert **TCVolts** (or each element of **TCVoltBuf**) into a corresponding temperature after performing the necessary cold-junction compensation. Cold-junction compensation is done by converting **CJCTemp** into an equivalent thermocouple voltage and adding it to **TCVolts**. The actual temperature-to-voltage conversion is done by choosing the appropriate reference equation that characterizes the correct temperature subrange for the specific **TCType**. The valid temperature range for a given **TCType** is divided into several subranges with each subrange characterized by a reference equation. The computed voltage is then added to **TCVolts** to perform the cold-junction correction. The conversion of **TCVolts** into a corresponding temperature is done by using inverse equations that are specified for a given **TCType** for different subranges. These inverse equations have an error tolerance as shown in

Table 5-1. All the reference equations and inverse equations used in these routines are from *NIST Monograph 175*.

Table 5-1 shows the valid temperature ranges and accuracies for the inverse equations used for each thermocouple type. The errors listed in the table refer to the equations only; they do not take into consideration the accuracy of the thermocouple itself, the SCXI modules, or the DAQ device that is used to take the voltage reading.

Table 5-1. Temperature Error for Thermocouple Inverse Equations

Thermocouple Type	Temperature Range	Error
B	250 to 700 °C	−0.02 to +0.03 °C
	700 to 1,820 °C	−0.01 to +0.02 °C
E	−200 to 0 °C	−0.01 to +0.03 °C
	0 to 1,000 °C	±0.02 °C
J	−210 to 0 °C	−0.05 to +0.03 °C
	0 to 760 °C	±0.04 °C
	760 to 1,200 °C	−0.04 to +0.03 °C
K	−200 to 0 °C	−0.02 to +0.04 °C
	0 to 500 °C	−0.05 to +0.04 °C
	500 to 1,372 °C	−0.05 to +0.06 °C
N	−200 to 0 °C	−0.02 to +0.03 °C
	0 to 600 °C	−0.02 to +0.03 °C
	600 to 1,300 °C	−0.04 to +0.02 °C
R	−50 to 250 °C	±0.02 °C
	250 to 1,200 °C	±0.005 °C
	1,200 to 1,664.5 °C	−0.0005 to +0.001 °C
	1,664.5 to 1,768.1 °C	−0.001 to +0.002 °C
S	−50 to 250 °C	±0.02 °C
	250 to 1,200 °C	±0.01 °C
	1,200 to 1,664.5 °C	±0.0002 °C
	1,664.5 to 1,768.1 °C	±0.002 °C
T	−200 to 0 °C	−0.02 to +0.04 °C
	0 to 400 °C	±0.03 °C

Technical Support and Professional Services

Visit the following sections of the National Instruments Web site at ni.com for technical support and professional services:

- **Support**—Online technical support resources include the following:
 - **Self-Help Resources**—For immediate answers and solutions, visit our extensive library of technical support resources available in English, Japanese, and Spanish at ni.com/support. These resources are available for most products at no cost to registered users and include software drivers and updates, a KnowledgeBase, product manuals, step-by-step troubleshooting wizards, hardware schematics and conformity documentation, example code, tutorials and application notes, instrument drivers, discussion forums, a measurement glossary, and so on.
 - **Assisted Support Options**—Contact NI engineers and other measurement and automation professionals by visiting ni.com/ask. Our online system helps you define your question and connects you to the experts by phone, discussion forum, or email.
- **Training**—Visit ni.com/custed for self-paced tutorials, videos, and interactive CDs. You also can register for instructor-led, hands-on courses at locations around the world.
- **System Integration**—If you have time constraints, limited in-house technical resources, or other project challenges, NI Alliance Program members can help. To learn more, call your local NI office or visit ni.com/alliance.

If you searched ni.com and could not find the answers you need, contact your local office or NI corporate headquarters. Phone numbers for our worldwide offices are listed at the front of this manual. You also can visit the Worldwide Offices section of ni.com/niglobal to access the branch office Web sites, which provide up-to-date contact information, support phone numbers, email addresses, and current events.

Glossary

Prefix	Meaning	Value
μ -	micro-	10^{-6}
m-	milli-	10^{-3}
k-	kilo-	10^3
M-	mega-	10^6

Symbols/Numbers

β coefficient

∂ coefficient

$^{\circ}$ degree

– minus

– plus

\pm plus or minus

ϵ strain

α temperature coefficient at $T = 0^{\circ}\text{C}$

1102/B/C modules refers to the SCXI-1102, SCXI-1102B, and SCXI-1102C modules

44XX device refers to the PCI-4451, PCI-4452, PCI-4454, PCI-4472, PXI-4472, and PCI-4474

45XX device refers to the PCI-4551 and PCI-4552

6025E device refers to the PCI-6025E and PXI-6025E

6052E device	refers to the PCI-6052E, PXI-6052E, and DAQPad-6052E for FireWire
61XX device	refers to the PCI-6110, PCI-6111, PCI-6115, PXI-6115, PCI-6120, and PXI-6120
652X device	refers to the PCI-6527 and PXI-6527
653X device	refers to the AT-DIO-32HS, PCI-DIO-32HS, DAQCard-6533, PXI-6533, PCI-6534, and PXI-6534
660X device	refers to the DAQCard-6601, PCI-6601, PCI-6602, PXI-6602, PCI-6608, and PXI-6608
6602 device	refers to the PCI-6602 and PXI-6602
671X device	refers to the DAQCard-6715, PCI-6711, PXI-6711, PCI-6713, and PXI-6713
673X devices	refers to the PCI-6731, PXI-6731, PCI-6733, and PXI-6733

A

A/D	analog-to-digital
AC	alternating current
ACK	acknowledge
ActiveX	a programming system and user interface that lets you work with interactive objects. Formerly called OLE.
ActiveX control	a standard software tool that adds additional functionality to any compatible ActiveX container
ADC	A/D converter—an electronic device, often an integrated circuit, that converts an analog voltage to a digital number
ADC resolution	the resolution of the ADC, which is measured in bits. An ADC with 16 bits has a higher resolution, and thus a higher degree of accuracy, than a 12-bit ADC.
AI	analog input
AMD	Advanced Micro Devices

analog trigger a trigger that occurs at a user-selected point on an incoming analog signal. Triggering can be set to occur at a specific level on either an increasing or a decreasing signal (positive or negative slope). Analog triggering can be implemented either in software or in hardware. When implemented in software (LabVIEW), all data is collected, transferred into system memory, and analyzed for the trigger condition. When analog triggering is implemented in hardware, no data is transferred to system memory until the trigger condition has occurred.

API application programming interface

ARB pertaining to arbitrary waveform generation (NI 54XX devices only)

asynchronous (1) hardware—a property of an event that occurs at an arbitrary time, without synchronization to a reference clock;
(2) software—an action or event that occurs at an unpredictable time with respect to the execution of a program

B

background acquisition data is acquired by a DAQ system while another program or processing routine is running without apparent interruption

bandwidth the range of frequencies present in a signal, or the range of frequencies to which a measuring device can respond

base address a memory address that serves as the starting address for programmable registers. All other addresses are located by adding to the base address.

BCD binary-coded decimal

BIOS basic input/output system

bipolar a signal range that includes both positive and negative values (for example, –5 V to +5 V)

bit one binary digit, either 0 or 1

block-mode a high-speed data transfer in which the address of the data is sent followed by a specified number of back-to-back data words

bus the group of conductors that interconnect individual circuitry in a computer. Typically, a bus is the expansion vehicle to which I/O or other devices are connected. Examples of PC buses are the PCI bus, AT bus, and EISA bus.

byte eight related bits of data, an 8-bit binary number. Also used to denote the amount of memory required to store one byte of data.

C

C Celsius

CI computing index

cold-junction compensation a method of compensating for inaccuracies in thermocouple circuits

compiler a software utility that converts a source program in a high-level programming language, such as C/C++, Visual Basic (version 5.0), or Borland Delphi, into an object or compiled program in machine language. Compiled programs run 10 to 1,000 times faster than interpreted programs.

conversion time the time required, in an analog input or output system, from the moment a channel is interrogated (such as with a read instruction) to the moment that accurate data is available

counter/timer a circuit that counts external pulses or clock pulses (timing)

coupling the manner in which a signal is connected from one location to another

CPU central processing unit

D

D/A digital-to-analog

DAC D/A converter—an electronic device, often an integrated circuit, that converts a digital number into a corresponding analog voltage or current

DAQ (1) data acquisition—collecting and measuring electrical signals from sensors, transducers, and test probes or fixtures and inputting them to a computer for processing;
(2) data acquisition—collecting and measuring the same kinds of electrical signals with A/D and/or DIO devices plugged into a computer, and possibly generating control signals with D/A and/or DIO devices in the same computer

DC	direct current
DDS	Direct Digital Synthesis
device	a plug-in DAQ board, card, or pad that can contain multiple channels and conversion devices. Plug-in boards and PCMCIA cards are all examples of DAQ devices. SCXI modules are distinct from devices.
differential input	an analog input consisting of two terminals, both of which are isolated from computer ground, whose difference is measured
digital port	<i>See</i> port .
DIN	Deutsche Industrie Norme (German Industrial Standard)
DIO	digital I/O
DIO device	refers to any DIO-24, DIO-32, DIO-6533, or DIO-96
DIO-24	refers to the PC-DIO-24, PC-DIO-24PnP, DAQCard-DIO-24, PCI-6503
DIO-32F	refers to the AT-DIO-32F
DIO-96	refers to the PC-DIO-96, PC-DIO-96PnP, PCI-DIO-96, DAQPad-6507, DAQPad-6508, and PXI-6508
dithering	the addition of Gaussian noise to the analog input signal
DLL	dynamic-link library—a software module in Microsoft Windows containing executable code and data that can be called or used by Windows applications or other DLLs. Functions and data in a DLL are loaded and linked at run time when they are referenced by a Windows application or other DLLs.
DMA	direct memory access—a method by which data can be transferred to/from computer memory from/to a device or memory on the bus while the processor does something else. DMA is the fastest method of transferring data to/from computer memory.
driver	software that controls a specific hardware device such as a DAQ board or a GPIB interface board
DSA	dynamic signal acquisition

DSA device	refers to the PCI-4451, PCI-4452, PCI 4454, PCI-4472, PCI-4551, PCI-4552, PXI-4472, and PCI-4474 dynamic signal acquisition devices
DSP	digital signal processing
DSUB	D-subminiature connector

E

EEPROM	electronically erasable programmable read-only memory—ROM that can be erased with an electrical signal and reprogrammed
EGA	Enhanced Graphics Adapter
EISA	Extended Industry Standard Architecture
E Series device	refers to MIO and AI devices
event-driven message	a message sent by an event-driven program, a program with a loop that waits for events to occur
external trigger	a voltage pulse from an external source that triggers an event such as A/D conversion

F

FIFO	a first-in first-out memory buffer; the first data stored is the first data sent to the acceptor. FIFOs are often used on DAQ devices to temporarily store incoming or outgoing data until that data can be retrieved or output. For example, an analog input FIFO stores the results of A/D conversions until the data can be retrieved into system memory, a process that requires the servicing of interrupts and often the programming of the DMA controller. This process can take several milliseconds in some cases. During this time, data accumulates in the FIFO for future retrieval. With a larger FIFO, longer latencies can be tolerated. In the case of analog output, a FIFO permits faster update rates, because the waveform data can be stored on the FIFO ahead of time. This again reduces the effect of latencies associated with getting the data from system memory to the DAQ device.
FireWire	refers to a high-speed external <i>bus</i> that implements the <i>IEEE</i> 1394 serial bus protocol

G

gain	the factor by which a signal is amplified, sometimes expressed in decibels
group	a collection of digital ports, combined to form a larger entity for digital input and/or output
GPS	Global Positioning System—a satellite-based system created and maintained by the U.S. Department of Defense that allows its users to determine their position, velocity, and time.
GPS receiver	an instrument that receives signals from GPS satellites
GUI	graphical user interface

H

Hz	hertz
----	-------

I

I/O	input/output
ID	identification
IDE	Integrated Development Environment
IEEE	Institute of Electrical and Electronics Engineers
import library	a file that contains information the linker needs to resolve external references to exported dynamic link library (DLL) functions, so the system can locate the specified DLL and exported DLL functions at run time
interrupt	a computer signal indicating that the CPU should suspend its current task to service a designated activity
interrupt latency	the delay between the time hardware asserts an interrupt and when the interrupt service routine is activated
IRIG	Inter Range Instrumentation Group—a pulse-modulated signal normally produced by a GPS receiver.
IRQ	interrupt request

ISA Industry Standard Architecture

iterations repetitions of the buffer

J

Julian a measurement of time based on the Julian calendar, a commonly used calendar that divides each year into 12 months with 365 days

K

kS 1,000 samples

Kword 1,024 words of memory

L

linker a software utility that combines object modules (created by a compiler) and libraries, which are collections of object modules, into an executable program

LSB least significant bit

M

master/slave type of network connection in which a request is transmitted to one or more destination nodes, and those nodes send a response back to the requesting node. In industrial applications, the responding (slave) device is usually a sensor or actuator, and the requesting (master) device is usually a controller.

MAX Measurement & Automation Explorer

MB megabytes of memory

MIO multifunction I/O

MIO device refers to multifunction I/O devices

MIO-16XE-50 device refers to the AT-MIO-16XE-50 and PCI-6070E (PCI-MIO-16XE-50)

MIO-64	refers to the AT-MIO-64E-3, PCI-6031E, and PCI-6071E
MS	million samples
MSB	most significant bit
multirate scanning	scanning different channels at different rates
mux	multiplexer—a switching device with multiple inputs that sequentially connects each of its inputs to its output, typically at high speeds, in order to measure several signals with a single analog input channel

N

NC	normally closed
NI	National Instruments
NI-DAQ	refers to the NI-DAQ software, unless otherwise noted
NI-TIO based device	refers to the NI 4551, NI 4552, DAQCard-6601, PCI-6601, PCI-6602, PXI-6602, PCI-6608, PXI-6608
NO	normally open

O

OCX	OLE Control eXtension—another name for OLE or ActiveX controls, reflected by the .OCX file extension of ActiveX control files.
output settling time	the amount of time required for the analog output voltage to reach its final value within specified limits

P

paging	a technique used for extending the address range of a device to point into a larger address space
PC	(1) personal computer; (2) Refers to the IBM PC/XT, IBM PC AT, and compatible computers.
PCI	Peripheral Component Interconnect

PCI Series	refers to the National Instruments products that use the high-performance expansion bus architecture originally developed by Intel
port	a digital port, consisting of four or eight lines of digital input and/or output
posttriggering	the technique used on a DAQ board to acquire a programmed number of samples after trigger conditions are met
PPS	pulse per second. A signal normally produced by a GPS receiver.
pretriggering	the technique used on a DAQ board to keep a continuous buffer filled with data, so that when the trigger conditions are met, the sample includes the data leading up to the trigger condition
programmed I/O	the standard method a CPU uses to access an I/O device—each byte of data is read or written by the CPU
pts	points
PXI	PCI eXtensions for Instrumentation. PXI is an open specification that builds off the CompactPCI specification by adding instrumentation-specific features.

R

RAM	random-access memory
REQ	request
resolution	The smallest signal increment that can be detected by a measurement system. Resolution can be expressed in bits, in proportions, or in percent of full scale. For example, a system has 12-bit resolution, one part in 4,096 resolution, and 0.0244% of full scale.
ROM	read-only memory
RTC	real time clock—a clock capable of recording the exact time of events that counts time in days, hours, minutes, seconds, and fractions of seconds.
RTD	Resistive Temperature Detector—a metallic probe that measures temperature based upon its coefficient of resistivity

RTSI Real-Time System Integration (bus)—the National Instruments timing bus that connects DAQ devices directly, by means of connectors on top of the boards, for precise synchronization of functions

S

S/s samples per second—used to express the rate at which a DAQ device samples an analog signal

s seconds

S samples

Sample-and-Hold (S/H) a circuit that acquires and stores an analog voltage on a capacitor for a short period of time

SCXI Signal Conditioning eXtensions for Instrumentation—the National Instruments product line for conditioning low-level signals within an external chassis near sensors

SCXI-1102/B/C refers to the SCXI-1102, SCXI-1102B, and SCXI-1102C

SCXI-1120/D refers to the SCXI-1120 and SCXI-1120D

SCXI-1104/C refers to the SCXI-1104 and SCXI-1104C

SCXI analog input module refers to the SCXI-1100, SCXI-1101, SCXI-1102, SCXI-1104, SCXI-1104C, SCXI-1112, SCXI-1120, SCXI-1120D, SCXI-1121, SCXI-1122, SCXI-1125, SCXI-1140, SCXI-1141, SCXI-1142, SCXI-1143, and SCXI-1520

SCXI analog output module refers to the SCXI-1124 module

SCXI chassis refers to the SCXI-1000, SCXI-1000DC, and SCXI-1001

SCXI digital module refers to the SCXI-1160, SCXI-1161, SCXI-1162, SCXI-1162HV, SCXI-1163, and SCXI-1163R

SCXI switch module refers to the SCXI-1127, SCXI-1128, SCXI-1129, SCXI-1160, SCXI-1161, SCXI-1163R, SCXI-1190, SCXI-1191, and SCXI-1192

SDK Software Development Kit

self-calibrating	a property of a DAQ device that has an extremely stable onboard reference and calibrates its own A/D and D/A circuits without manual adjustments by the user
simultaneous sampling module	refers to the PCI-6110, PCI-6111, PCI-6115, PXI-6115, PCI-6120, PXI-6120, PCI-4451, PCI-4452, PCI-4454, PCI-4551, PCI-4552, PCI-4472, PXI-4472, and PCI-4474
Single-Ended (SE) Inputs	an analog input that is measured with respect to a common ground
slave	See master/slave .
software trigger	a programmed event that triggers an event such as data acquisition
stage	(NI 54XX boards only) an entry in a sequence list
STC	System Timing Controller
synchronous	(1) hardware—a property of an event that is synchronized to a reference clock; (2) software—a property of a function that begins an operation and returns only when the operation is complete

T

TC	terminal count
throughput rate	the data, measured in bytes/s, for a given continuous operation, calculated to include software overhead
track-and-hold module	refers to the SCXI-1140, SCXI-1520, SCXI-1530, and SCXI-1531
Traditional NI-DAQ	refers to the Traditional NI-DAQ software, unless otherwise noted
transfer rate	the rate, measured in bytes/s, at which data is moved from source to destination after software initialization and set up operations; the maximum rate at which the hardware can operate
TSR	Terminate-and-Stay Resident

U

unipolar	a signal range that is always positive (for example, 0 to +10 V)
USB	universal serial bus

V

V	volt
VDC	volts direct current
VPICD	Virtual Programmable Interrupt Controller Device
